Preface

The notes have been used as the introductory section of a course on Modern Organic Synthesis that composes 6 weeks or a little more than one-half of a quarter course at The Scripps Research Institute, Department of Chemistry. Consequently, an exhaustive treatment of the individual topics is beyond the scope of this portion of the course. The remaining 4 weeks of the quarter delve into more detail on various topics and introduce concepts in multistep organic synthesis (E. Sorensen). For our students, this is accompanied by a full quarter course in physical organic chemistry and is followed by a full quarter course on state of the art natural products total synthesis (K. C. Nicolaou, E. Sorensen) and a quarter elective course on transition metal chemistry. Complementary to these synthetic and mechanistic courses, two quarter courses on bioorganic chemsitry and an elective course on the principles of molecular biology and immunology are available to our students. Efforts have been made to not duplicate the content of these courses. For those who might examine or use the notes, I apologize for the inevitable oversight of seminal work, the misattribution of credit, and the missing citations to work presented. The original notes were not assembled with special attention to this detail, but rather for the basic content and the 'nuts and bolts' laboratory elements of organic synthesis. In addition, some efforts were made to highlight the chemistry and contributions of my group and those of my colleagues for the intrinsic interest and general appreciation of our students. I hope this is not mistaken for an effort to unduly attribute credit where this was not intended. We welcome any suggestions for content additions or corrections and we would be especially pleased to receive even minor corrections that you might find. - Dale L. Boger

Acknowledgments

Significant elements of the material in the notes were obtained from the graduate level organic synthesis course notes of P. Fuchs (Purdue University) and were influenced by my own graduate level course taught by E. J. Corey (Harvard). They represent a set of course notes that continue to evolve as a consequence of the pleasure of introducing young colleagues to the essence and breadth of modern organic synthesis and I thank them for the opportunity, incentive, and stimulation that led to the assemblage of the notes. Those familiar with ChemDraw know the efforts that went into reducing my hand drafted notes and those maintained by Robert J. Mathvink (Purdue University) and Jiacheng Zhou (The Scripps Research Institute) to a ChemDraw representation. For this, I would like to thank Robert M. Garbaccio for initiating, coordinating, proofing and driving the efforts, and Steve, Richard, Chris, Bryan, Clark, Marc, Jason, Rob, Wenge, Jiyong, Brian, Mark, Gordon, Robert and Joel for reducing the painful task to a reality.

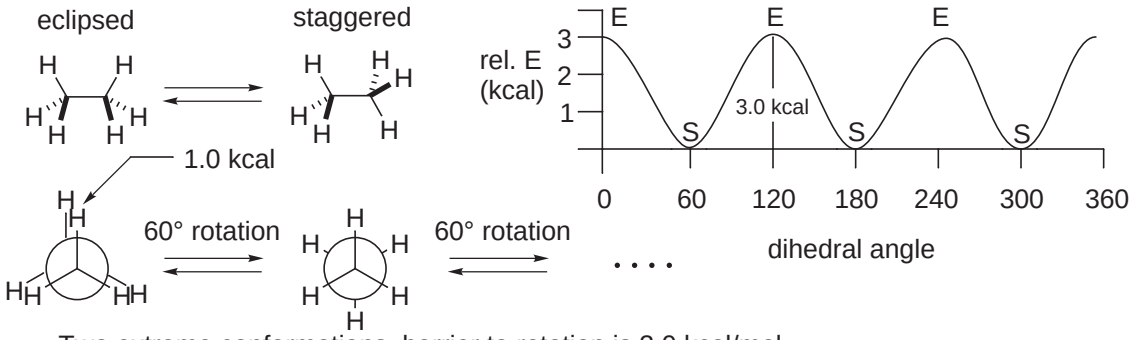
It is a pleasure to dedicate this book and set of notes to Richard Lerner who is responsible for their appearance. His vision to create a chemistry program within Scripps, his energy and enthusiasm that brought it to fruition, his support for the graduate program and committment to its excellence, and his personal encouragement to this particular endeavour of developing a graduate level teaching tool for organic synthesis, which dates back to 1991, made this a reality.

Table of Contents

I. Conformational Analysis

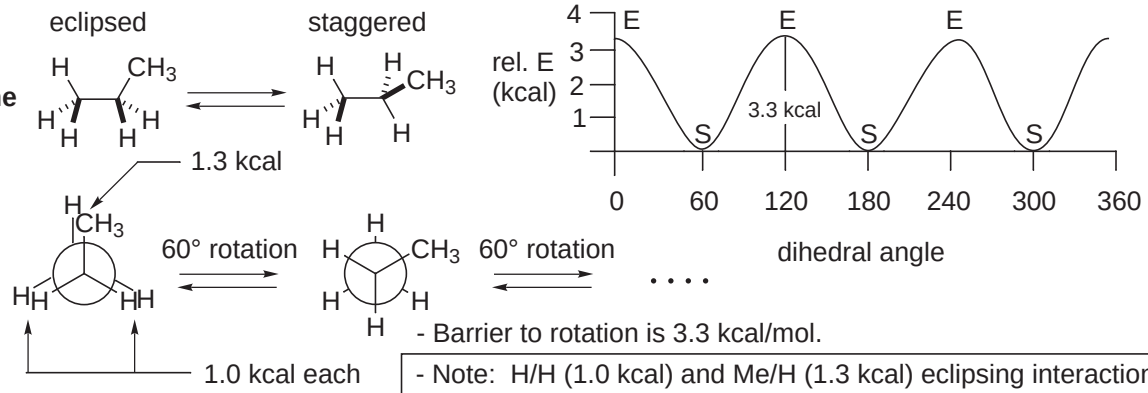
A. Acyclic sp^3-sp^3 Systems: Ethane, Propane, Butane

1. Ethane



- Two extreme conformations, barrier to rotation is 3.0 kcal/mol.

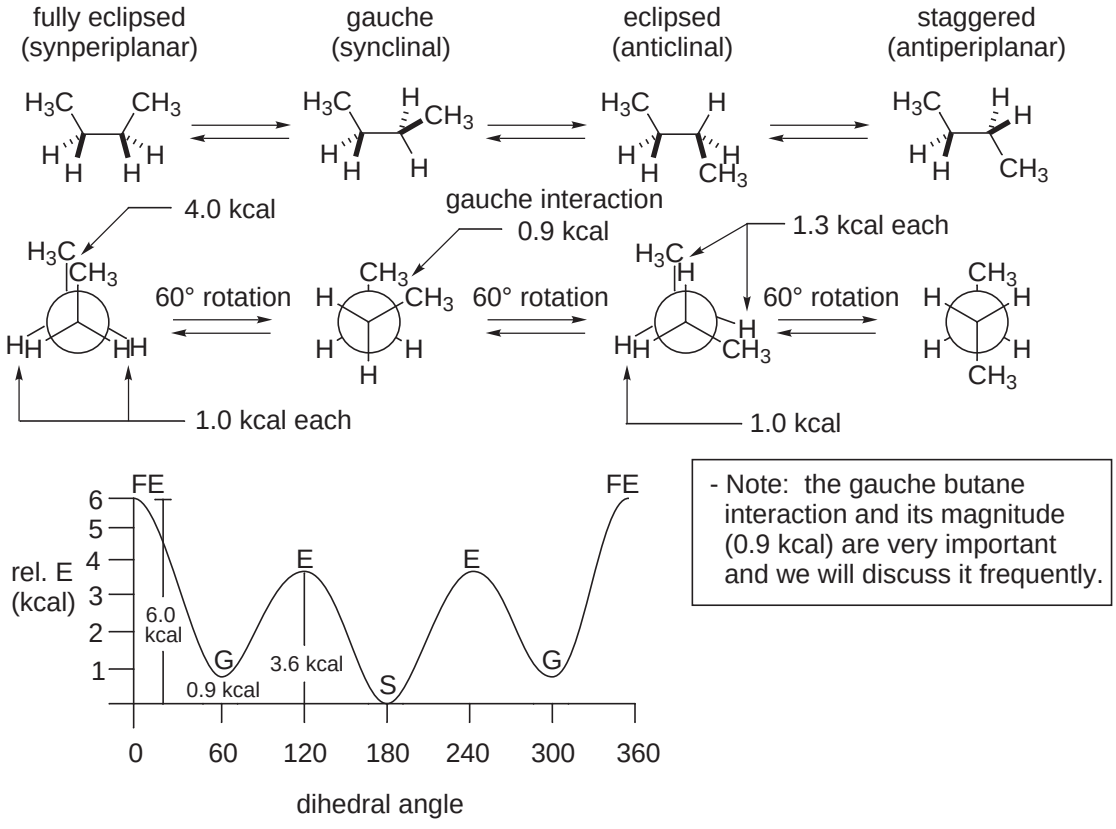
2. Propane



- Barrier to rotation is 3.3 kcal/mol.

- Note: H/H (1.0 kcal) and Me/H (1.3 kcal) eclipsing interactions are comparable and this is important in our discussions of torsional strain.

3. Butane



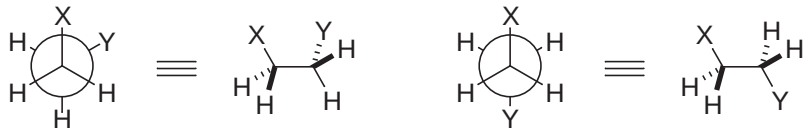
- Note: the gauche butane interaction and its magnitude (0.9 kcal) are very important and we will discuss it frequently.

First Edition 1999 (Version 1.0)

Printed and Bound in the U.S.A. by Rush Press, San Diego, California

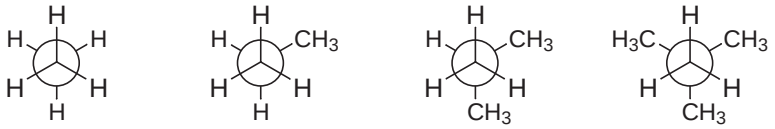
4. Substituted Ethanes

- There are some exceptions to the lowest energy conformation. Sometimes, a gauche conformation is preferred over staggered if X,Y are electronegative substituents.
cf: Kingsbury *J. Chem. Ed.* **1979**, *56*, 431.



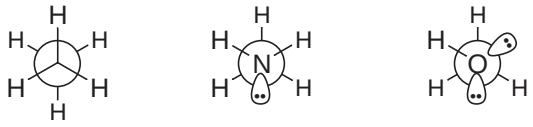
$E_{gauche} < E_{staggered}$ if X = OH, OAc and Y = Cl, F

5. Rotational Barriers



2.88 kcal/mol	3.40 kcal/mol	3.90 kcal/mol	4.70 kcal/mol	- Experimental
(3.0 kcal/mol	3.3 kcal/mol	3.6 kcal/mol	3.9 kcal/mol)	- Simple prediction

- The rotational barrier increases with the number of CH_3/H eclipsing interactions.

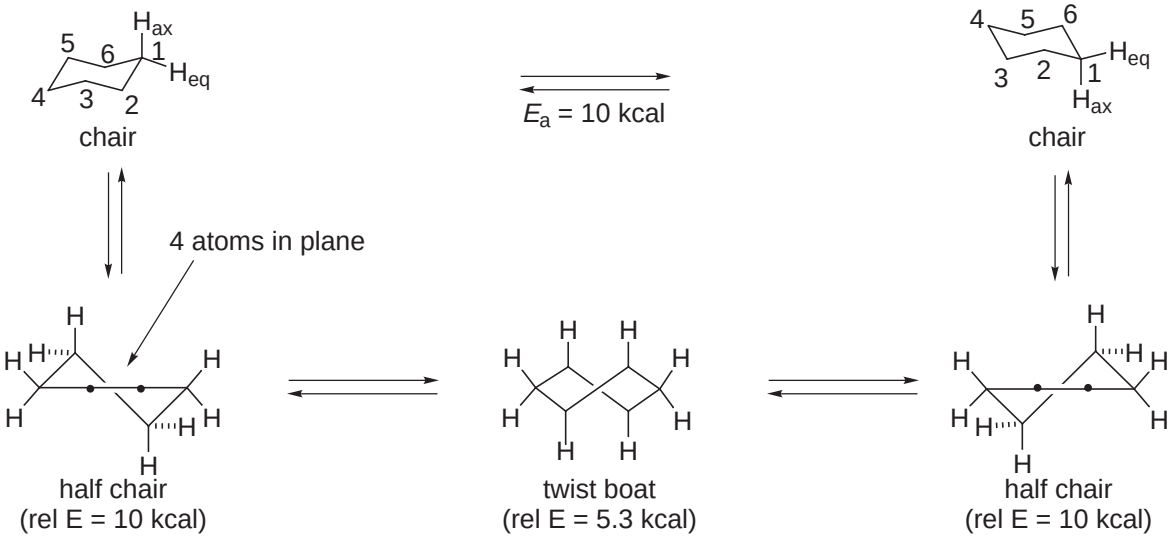


2.88 kcal/mol	1.98 kcal/mol	1.07 kcal/mol	- Experimental
(3.0 kcal/mol	2.0 kcal/mol	1.0 kcal/mol)	- Simple prediction

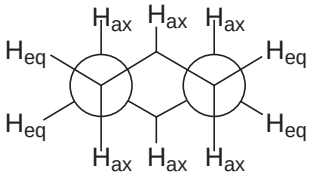
- The rotational barrier increases with the number of H/H eclipsing interactions.

B. Cyclohexane and Substituted Cyclohexanes, A Values ($\Delta G°$)

1. Cyclohexane

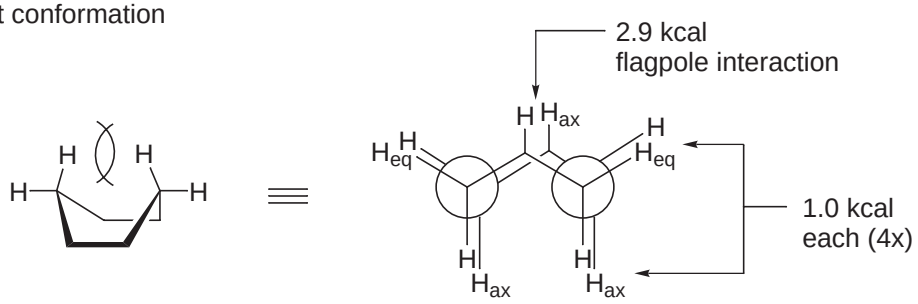


- Chair conformation (all bonds staggered)



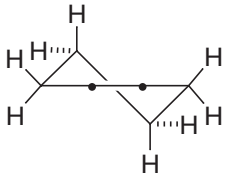
- Rapid interconversion at 25 °C (E_a = 10 kcal/mol, 20 kcal/mol available at 25 °C).
- H_{ax} and H_{eq} are indistinguishable by ^{1}H NMR at 25 °C.
- At temperatures < –70 °C, H_{eq} and H_{ax} become distinct in ^{1}H NMR.

- Boat conformation

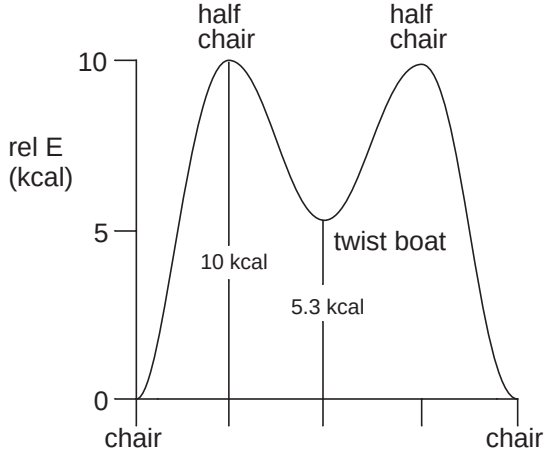


- Rel E = 6.9 kcal, not local minimum on energy surface.
- More stable boat can be obtained by twisting (relieves flagpole interaction somewhat).
- Twist boat conformation (rel E = 5.3 kcal) does represent an energy minimum.
- The boat conformation becomes realistic if flagpole interactions are removed, i.e.

- Half chair conformation



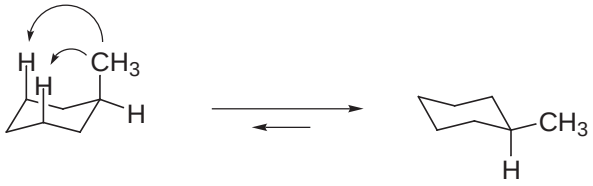
- Energy maximum (rel E = 10.0 kcal)



D.H.R. Barton received the 1969 Nobel Prize in Chemistry for his contributions to conformational analysis, especially as it relates to steroids and six-membered rings. Barton *Experientia* **1950**, *6*, 316.

2. Substituted Cyclohexanes

- Methylcyclohexane

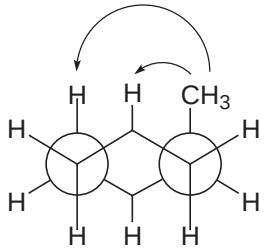


1.8 kcal more stable

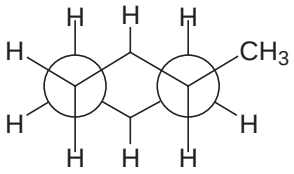
$$\Delta G° = -RT(\ln K)$$

$$\frac{1.8 \times 1000}{1.99 \times 298} = -\ln K$$

- The gauche butane interaction is most often identifiable as 1,3-diaxial interactions.



2 gauche butane interactions
2 x 0.9 kcal = 1.8 kcal
(experimental 1.8 kcal)



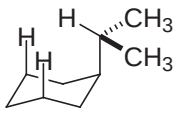
0 gauche butane interactions

- A Value ($-\Delta G°$) = Free energy difference between equatorial and axial substituent on a cyclohexane ring.

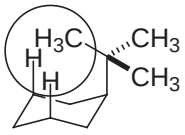
Typical A Values

R	A Value (kcal/mol)		R	A Value (kcal/mol)	
F	0.25		CN	0.2	Small, linear
Cl	0.52		$C\equiv CH$	0.41	groups
Br	0.5-0.6	ca. 0.5 kcal	NO_2	1.1	
I	0.46		$CH=CH_2$	1.7	
OH	0.7 (0.9)	ca. 0.7 kcal	CH_3	1.8	
OCH_3	0.75	(2^{nd} atom effect	CH_2CH_3	1.9 (1.8)	2^{nd} atom
$OCOCH_3$	0.71	very small)	$^nC_3H_7$	2.1	effect very
NH_2	1.8 (1.4)		$^nC_4H_9$	2.1	small
NR_2	2.1		$CH(CH_3)_2$	2.1	
CO_2H	1.2 (1.4)		$C(CH_3)_3$	>4.5 (ca. 5.4)	
CO_2Na	2.3		C_6H_5	3.1 (2.9)	
CO_2Et	1.1				
SO_2Ph	2.5				

- Note on difference between ^{i}Pr and ^{t}Bu A values.

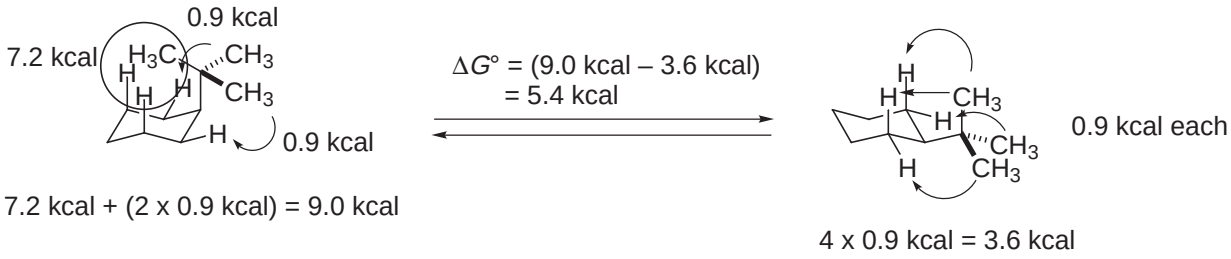


^{i}Pr group can position H toward "inside,"



but ^{t}Bu group cannot.
Very serious interaction, 7.2 kcal.

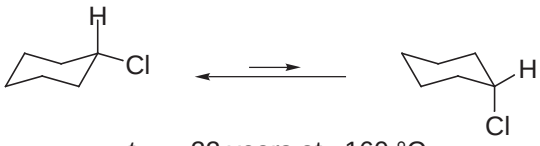
- Determination of A value for ^{t}Bu group.



7.2 kcal + (2 x 0.9 kcal) = 9.0 kcal

4 x 0.9 kcal = 3.6 kcal

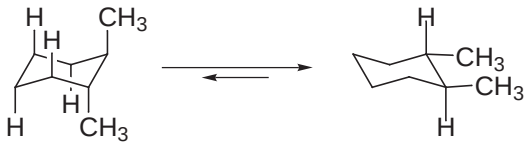
- Note on interconversion between axial and equatorial positions.



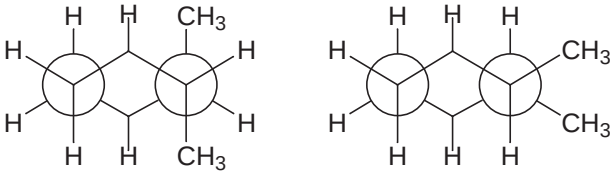
$t_{1/2}$ = 22 years at –160 °C

Even though Cl has a small A value (i.e., small $\Delta G°$ between rings with equatorial and axial Cl group), the E_a (energy of activation) is high (it must go through half chair conformation).

trans-1,2-dimethylcyclohexane



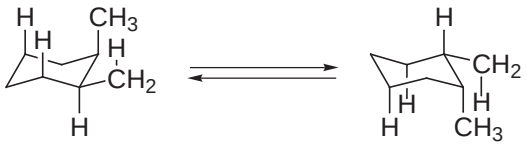
2.7 kcal/mol more stable



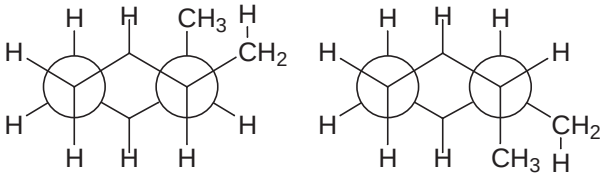
4 x (gauche interaction)
4 x (0.9 kcal) = 3.6 kcal

1 x (gauche interaction)
1 x (0.9 kcal) = 0.9 kcal

cis-1,2-dimethylcyclohexane

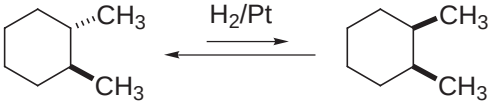


ΔE = 0 kcal/mol



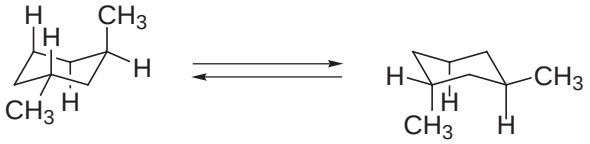
3 x (gauche interaction)
3 x (0.9 kcal) = 2.7 kcal

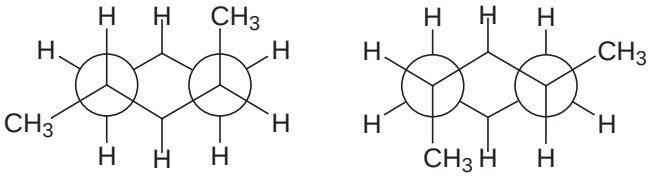
3 x (gauche interaction)
3 x (0.9 kcal) = 2.7 kcal



ΔG = 1.87 kcal/mol (exp)
ΔG = 1.80 kcal/mol (calcd)

trans-1,3-dimethylcyclohexane

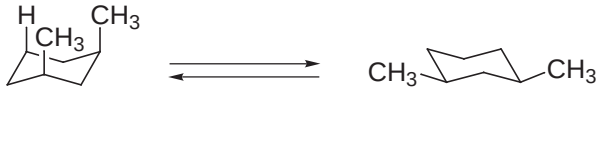


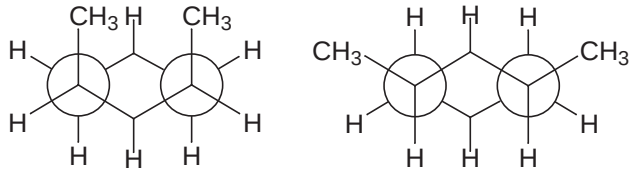


2 x (gauche interaction)
2 x (0.9 kcal) = 1.8 kcal

2 x (gauche interaction)
2 x (0.9 kcal) = 1.8 kcal

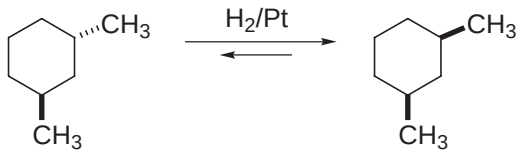
cis-1,3-dimethylcyclohexane





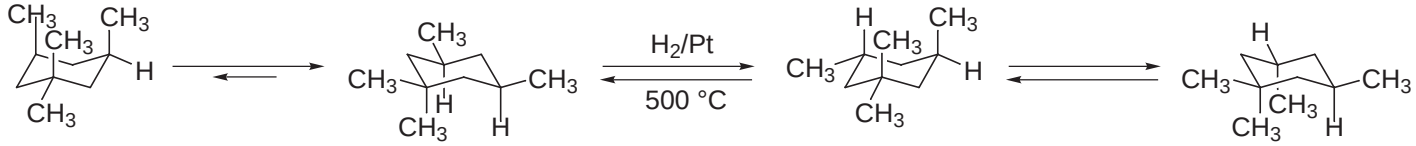
2 x (gauche interaction) +
1 x (Me-Me 1,3 diaxial int)
2 x (0.9 kcal) + 3.7 kcal
= 5.5 kcal

0 x (gauche interaction)
0 x (0.9 kcal) = 0 kcal



ΔG = 1.80 kcal/mol (exp and calcd)

- Determination of energy value of Me-Me 1,3-diaxial interaction.



3 x Me-Me 1,3-diaxial interaction

2 x (gauche interaction)
2 x (0.9 kcal) = 1.8 kcal

2 x (gauche interaction) +
1 x (Me-Me 1,3 diaxial int) =
2 x (0.9 kcal) + ?

2 x (gauche interaction) +
1 x (Me-Me 1,3 diaxial int) =
2 x (0.9 kcal) + ?

ΔG = 3.7 kcal/mol (exp)
So, Me-Me 1,3-diaxial interaction = 3.7 kcal/mol.

1,3-diaxial interactions

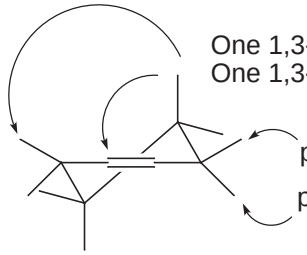
R/R	$\Delta G°$
OH/OH	1.9 kcal
OAc/OAc	2.0 kcal
OH/CH_3	2.4 (1.6) kcal
CH_3/CH_3	3.7 kcal

$\Delta G°$ of common interactions

	ax OH	ax CH_3	eq OH
ax H	0.45*	0.9	0.0
ax OH	1.9	1.6	0.35
eq OH	0.35	0.35	0.35
eq CH_3	0.35	0.9	0.35

*1/2 of A value

C. Cyclohexene

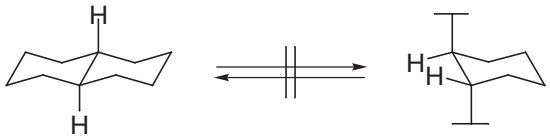


One 1,3-diaxial interaction removed
One 1,3-diaxial interaction reduced

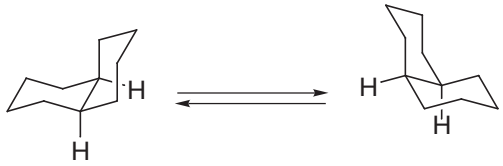
- half-chair
- E_a for ring interconversion = 5.3 kcal/mol
- the preference for equatorial orientation of a methyl group in cyclohexene is less than in cyclohexane because of the ring distortion and the removal of one 1,3-diaxial interaction (1 kcal/mol)

D. Decalins

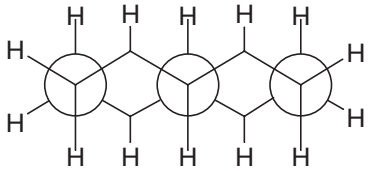
trans-decalin



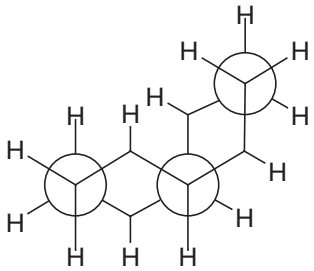
cis-decalin



two conformations equivalent



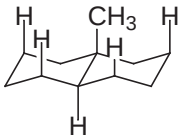
0.0 kcal



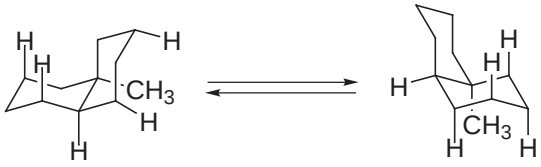
3 gauche interactions
3 x 0.9 kcal = 2.7 kcal

ΔE between *cis*- and *trans*-decalin = 2.7 kcal/mol

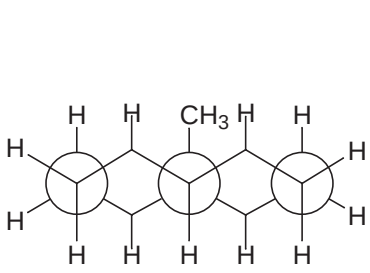
trans-9-methyldecalin



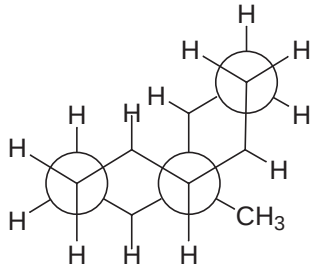
cis-9-methyldecalin



two conformations equivalent



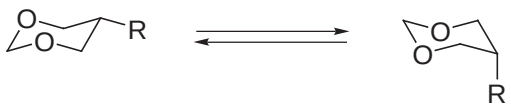
4 gauche interactions
4 x 0.9 = 3.6 kcal



5 gauche interactions
5 x 0.9 = 4.5 kcal

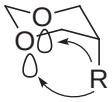
ΔE between *cis*- and *trans*-9-methyldecalin = 0.9 kcal/mol

E. 1,3-Dioxanes



- Less preference for R group to be equatorial because the lone pair has a smaller steric requirement than a C-H bond ($\Delta G°$ lower).

- In fact, some polar substituents (i.e. F, NO_2, $SOCH_3$, $^{+}NMe_3$, etc) prefer axial position.



F. Acyclic sp^3-sp^2 Systems

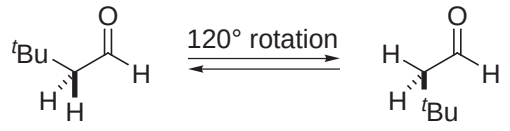
- *J. Am. Chem. Soc.* **1969**, *91*, 337.

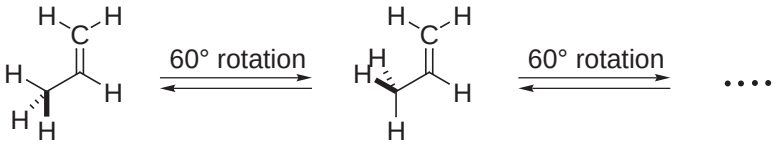


relative energies (kcal)

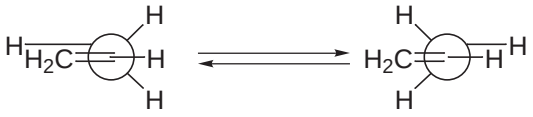
Exp	2.5	0.0

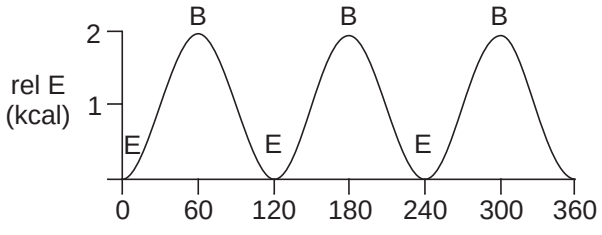
- Alkyl eclipsed conformation more stable than H-eclipsed and exceptions occur only if alkyl group is very bulky (i.e., ^{t}Bu).
- Because E differences are quite low, it is difficult to relate ground state conformation to experimental results. All will be populated at room temperature.

3. Propene



eclipsed bisected



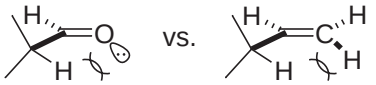


relative energies (kcal)

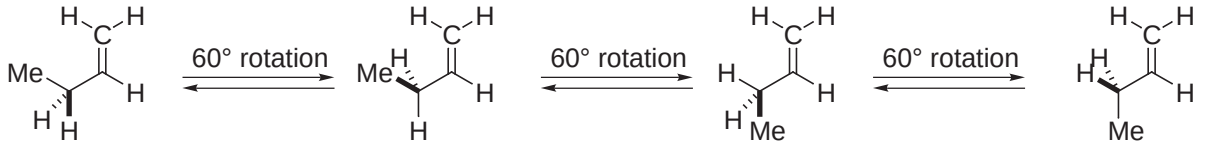
Exp	0.0	2.0
MM2	0.0	2.1–2.2

- Two extreme conformations
- Barrier to rotation is 2.0 kcal/mol

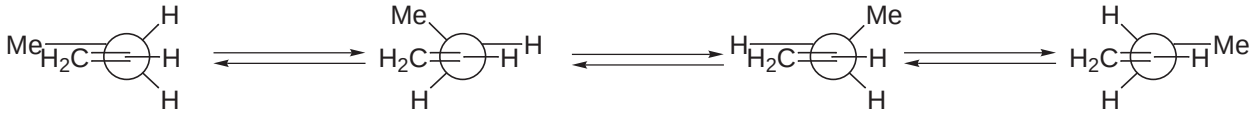
Note:



4. 1-Butene

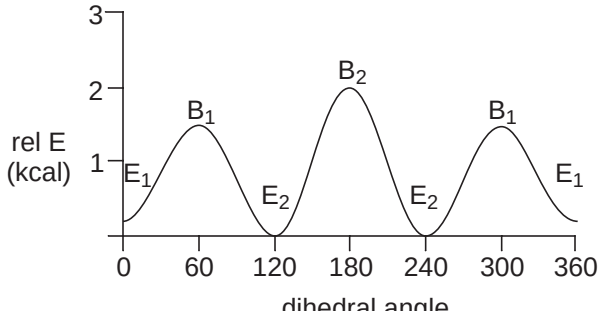


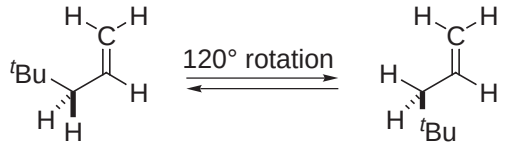
eclipsed bisected eclipsed bisected



relative energies (kcal)

Exp	0.0, 0.2, 0.4, 0.5	-	0.0	-
MM2	0.5, 0.7	1.4–1.7 (2.6)	0.0	1.4–1.8 (2.6)
Ab initio	0.6	-	0.0	2.0





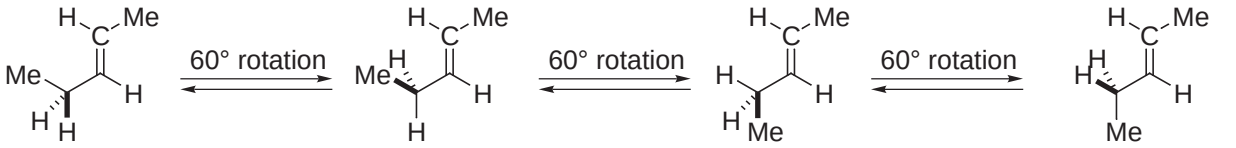
eclipsed (E_1) eclipsed (E_2)

relative energies (kcal)

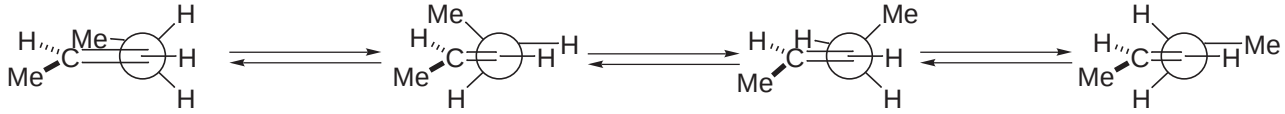
Exp	B_1, B_2 > E_1 >> E_2

- There is an additional destabilization of placing the alkyl group eclipsed with C=C. This is due to the larger steric size of olefinic CH compared to carbonyl C=O.
- The eclipsed conformations (even with an α-^{t}Bu) are both more stable than the bisected conformations.

5. *E*-2-Pentene

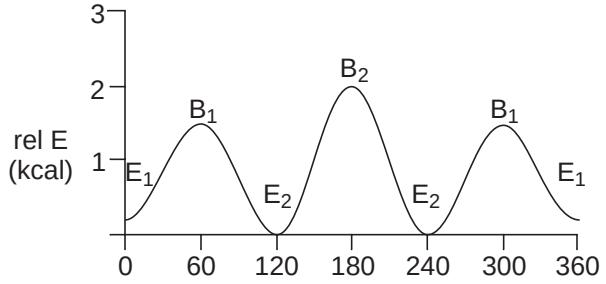


eclipsed bisected eclipsed bisected



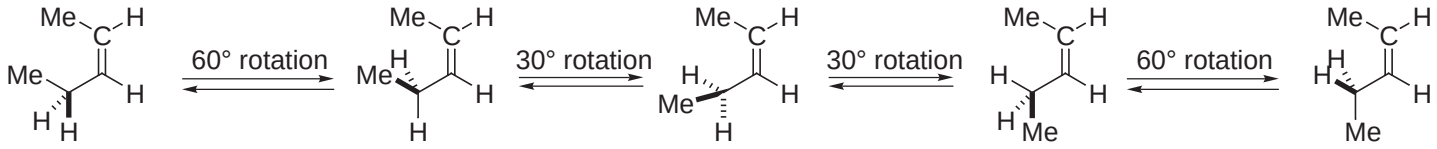
relative energies (kcal)

Exp	0.0 (0.0–0.4)	-	0.0	-
MM2	0.6	1.4–1.7 (2.6)	0.0	1.5–1.8 (2.6)

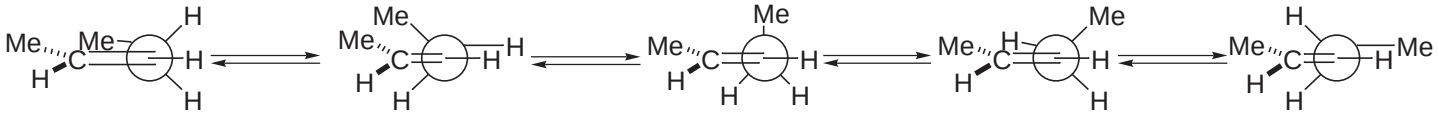


- Analogous to 1-butene.

6. *Z*-2-Pentene

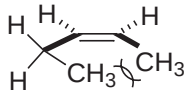


eclipsed bisected perpendicular eclipsed bisected

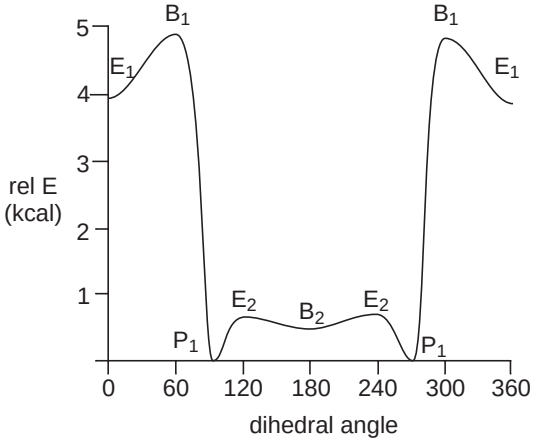


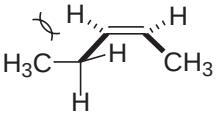
relative energies (kcal)

MM2	3.9	4.9	0.0	0.6	0.5



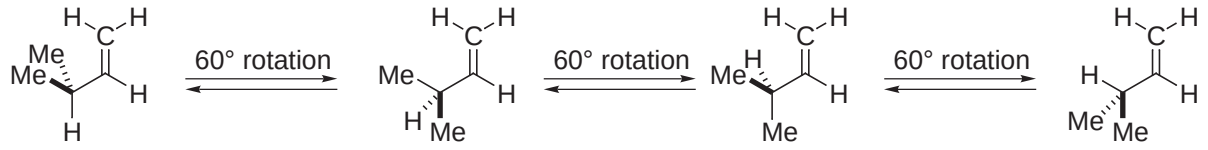
- Serious destabilizing interaction, often referred to as allylic 1,3-strain (A 1,3-strain).



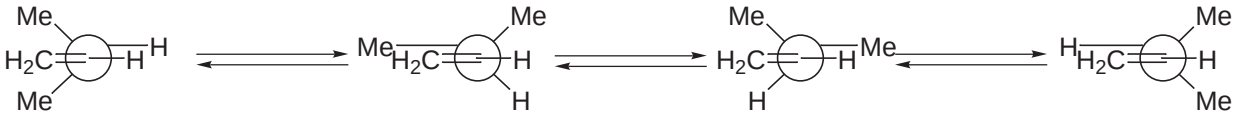


- The analogous H/CH_3 eclipsing interaction in the bisected conformation is often referred to as allylic 1,2-strain (A 1,2-strain).

7. 3-Methyl-1-butene

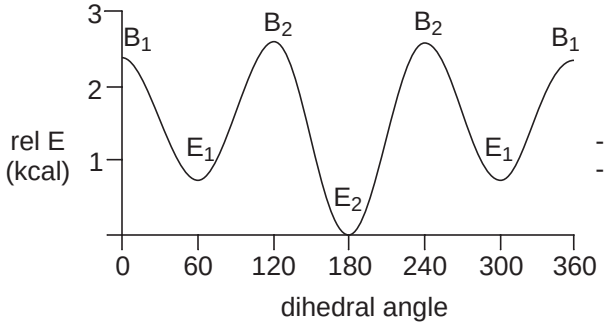


bisected — eclipsed — bisected — eclipsed



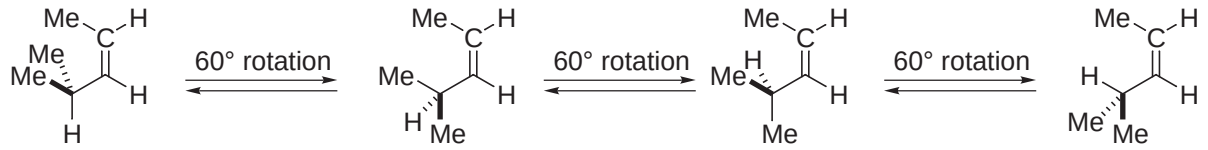
relative energies (kcal)

Ab initio	2.4–3.0	0.73–1.19	2.60–2.94	0.0

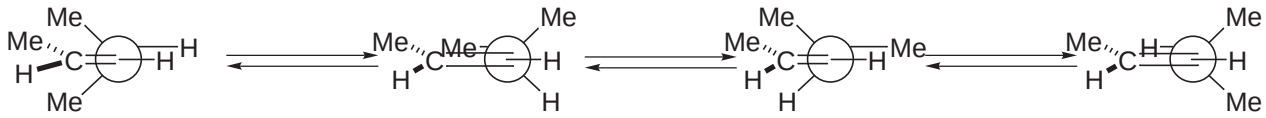


- *J. Am. Chem. Soc.* **1991**, *113*, 5006.
- *Chem. Rev.* **1989**, *89*, 1841.

8. 4-Methyl-2-pentene

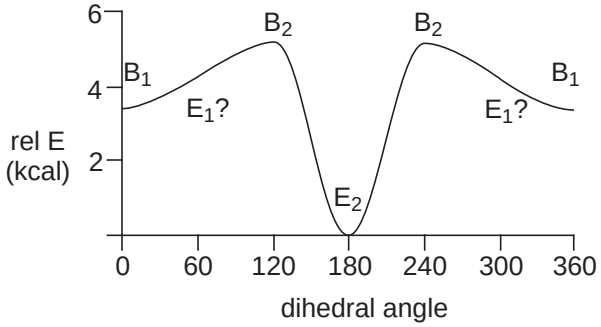


bisected — eclipsed — bisected — eclipsed



relative energies (kcal)

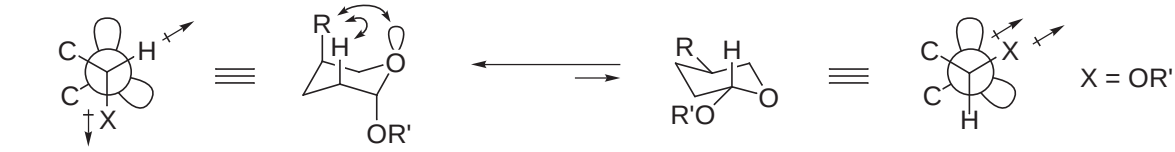
Ab initio	3.4–4.3	-	4.9–5.9	0.0



- Only H-eclipsed conformation is reasonable.

G. Anomeric Effect

1. Tetrahydropyrans (e.g., Carbohydrates)



Dipoles opposed → preferred

Dipoles aligned → destabilizing

R = H, preferred conformation. $\Delta G°$ = 0.85 kcal/mol

- generally 0–2 kcal/mol, depends on C2/C3 substituents
- effect greater in non-polar solvent

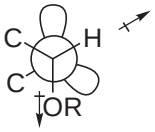
Comprehensive Org. Chem. Vol. 5, 695.
Comprehensive Het. Chem. Vol. 3, 629.
Review: *Tetrahedron* **1992**, *48*, 5019.

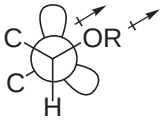
1. A value for R group will be smaller, less preference for equatorial vs axial C3 or C5 substituent since one 1,3-diaxial interaction is with a lone pair versus C–H bond.
2. Polar, electronegative group (e.g., OR and Cl) adjacent to oxygen prefers axial position.
3. Alkyl group adjacent to oxygen prefers equatorial position.
4. Electropositive group (such as $^{+}NR_3$, NO_2, $SOCH_3$) adjacent to oxygen strongly prefers equatorial position. ⇒ Reverse Anomeric Effect

- Explanations Advanced:

1. Dipole stabilization

opposing dipoles, stabilizing

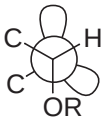


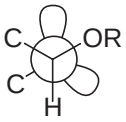


dipoles aligned, destabilizing

2. Electrostatic repulsion

minimizes electrostatic repulsion between lone pairs and the electronegative substituent



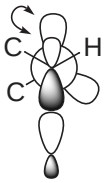


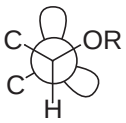
maximizes destabilizing electrostatic interaction between electronegative centers (charge repulsion)

3. Electronic stabilization

σ*– n orbital stabilizing interaction

n electron delocalization into σ* orbital

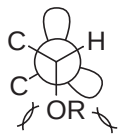


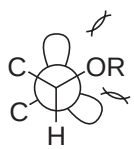


no stabilization possible

4. Gauche interaction involving lone pairs is large (i.e. steric)

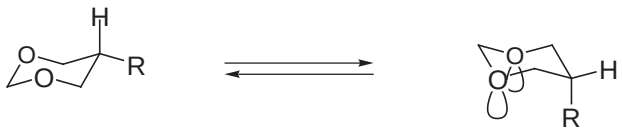
1 lone pair / OR gauche interaction + 1 C/OR gauche interaction (0.35 kcal/mol)





2 lone pair / OR gauche interactions, but would require that they be ~1.2 kcal/mol

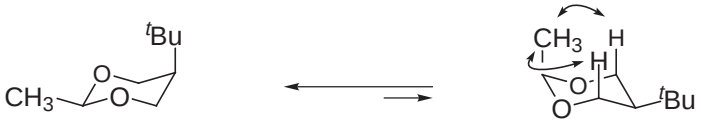
2. Anomeric Effect and 1,3-Dioxanes



lone pair / R interaction

1. Polar, electronegative C2/C4 substituents prefer axial orientation.
2. The lone pair on oxygen has a smaller steric requirement than a C–H bond.

   $\Delta G°$ is much lower, lower preference between axial and equatorial C5 substituent
3. Polar electropositive groups C2 equatorial position preferred:
   C5 axial position may be preferred for F, NO_2, $SOCH_3$, $^{+}NMe_3$.



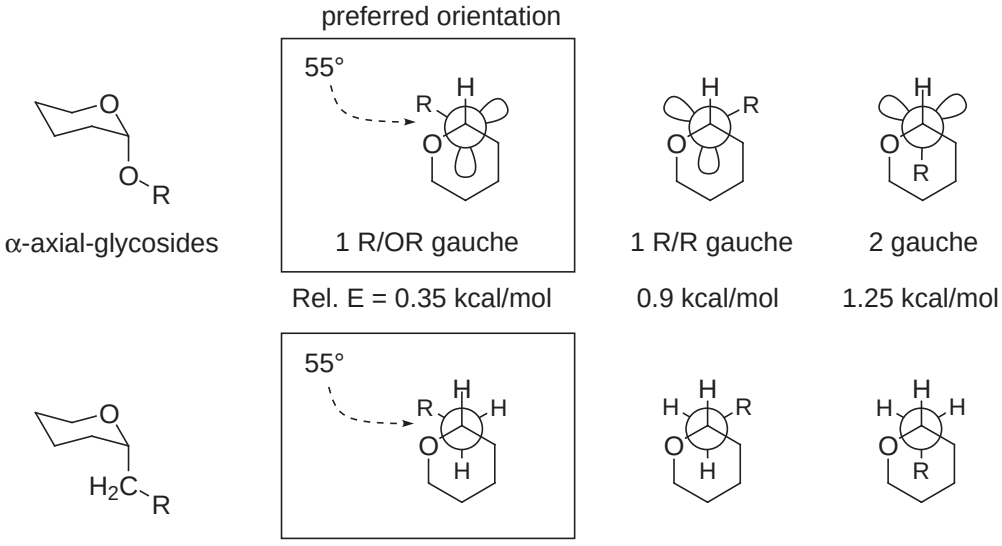
preferred
conformation

Eliel *J. Am. Chem. Soc.* **1968**, *90*, 3444.

A Value (kcal/mol) for Substituents on Tetrahydropyran and 1,3-Dioxane versus Cyclohexane

Group	Cyclohexane	Tetrahydropyran C2	1,3-Dioxane C2	1,3-Dioxane C5
CH_3	1.8	2.9	4.0	0.8
Et	1.8		4.0	0.7
^{i}Pr	2.1		4.2	1.0
^{t}Bu	>4.5			1.4

3. Exo Anomeric Effect



Kishi *J. Org. Chem.* **1991**, *56*, 6412.

H. Strain

Cyclic Hydrocarbon, Heats of Combustion/Methylene Group (gas phase)

Ring Size	$-\Delta H_c$ (kcal/mol)	Ring Size	$-\Delta H_c$ (kcal/mol)	
3	166.3	10	158.6	
4	163.9	11	158.4	
5	158.7	12	157.8	
strain free 6	157.4	13	157.7	
7	158.3	14	157.4	largely strain free
8	158.6	15	157.5	
9	158.8	16	157.5	

1. Small rings (3- and 4-membered rings): small angle strain

For cyclopropane, reduction of bond angle from ideal 109.5° to 60°
27.5 kcal/mol of strain energy.

For cyclopropene, reduction of bond angle from ideal 120° to 60°
52.6 kcal/mol of strain energy.

To form a small ring in synthetic sequences, must overcome the energy barrier implicated in forming a strained high energy product.

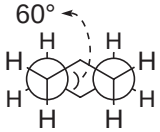
2. Common rings (5-, 6-, and 7-membered rings):
   - largely unstrained and the strain that is present is largely torsional strain (Pitzer strain).

3. Medium rings (8- to 11-membered rings):
   a. large angle strain
      - bond angles enlarged from ideal 109.5° to 115–120°.
      - bond angles enlarged to reduce transannular interactions.

   b. steric (transannular) interactions
      - analogous to 1,3-diaxial interactions in cyclohexanes, but can be 1,3-, 1,4-, or 1,5- ...

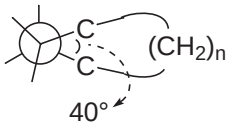
   c. torsional strain (Pitzer strain)

in cyclohexanes



just like gauche butane.

in medium rings
- deviation from ideal ϕ of 60° and approach an eclipsing interaction.



4. Large rings (12-membered and up):
   - little or no strain.

I. pK_a of Common Organic Acids

Acid	pK_a
cyclohexane	45
ethane	42
benzene	37
ethylene	36
Et_2NH	36
NH_3 (ammonia)	35
toluene, propene	35
$(C_6H_5)_3CH$	28–33
DMSO ($CH_3S(O)CH_3$)	31
$C_6H_5NH_2$	27
$HC{\equiv}CH$	25
CH_3CN	25
CH_3CO_2Et	25
$CH_3SO_2CH_3$	23–27
CH_3CONMe_2	25
aliphatic ketones	20–23
$(CH_3)_3CCOCH(CH_3)_2$	23
$(CH_3)_3CCOCH_3$	21
CH_3COCH_3	20
$CH_3COC_6H_5$	19
$(CH_3)_3COH$	19
$C_6H_5C{\equiv}CH$	19

Acid	pK_a
$(CH_3)_2CHOH$	18
CH_3CH_2OH	17
cyclic ketones	17
e.g. cyclohexanone	17
CH_3OH	16 (16–18)
$CH_3CONHCH_3$	16–17
$PhCH_2COPh$	16
H_2O	16
cyclopentadiene	15
$CH_2(CO_2Et)_2$	13
$CH_2(CN)_2$	11
$CH_3COCH_2CO_2Et$	11
CH_3NO_2	10
phenol	10
$R_3NH^+Cl^-$	10
HCN	9
$CH_3CH_2NO_2$	9
$CH_3COCH_2COCH_3$	9
$CH_2(CN)CO_2Et$	9
CH_3CO_2H	5
py•HCl	5
$C_6H_5NH_3^+Cl^-$	5

$$XH \rightleftharpoons H^+ + X^-$$

$$K_a = \frac{[H^+][X^-]}{[HX]}$$

$pK_a = -\log K_a = -\log[H^+]$
Increase in pK_a means decrease in $[H^+]$ and acidity
Decrease in pK_a means increase in $[H^+]$ and acidity

For more extensive lists, see:
The Chemist's Companion, p 584.
House, p 494.

Familiarity with these pK_a's will allow prediction/estimation of acidities of other compounds. This is important, since many organic reactions have a pK_a basis (i.e., enolate alkylations).

II. Kinetics and Thermodynamics of Organic Reactions

A. Free Energy Relationships

$$\Delta G = \Delta H - T\Delta S$$

The equilibrium for the reaction can be described by

$$\ln K_{eq} = -\frac{\Delta G}{RT}$$

To achieve a high ratio of two products (desired product and undesired product) in a thermodynamically controlled reaction (i.e. under reversible conditions) you need the following ΔG's:

K (25 °C)		ΔG (kcal/mol)	*K* (0 °C)		ΔG (kcal/mol)	*K* (–78 °C)		ΔG (kcal/mol)
2	(67:33)	0.41	2.1	(68:32)	0.41	2.9	(75:25)	0.41
5	(83:17)	0.95	5.7	(85:15)	0.95	11.6	(92:8)	0.95
9	(90:10)	1.30	10.9	(92:18)	1.30	28.5	(97:3)	1.30
20	(95:5)	1.74	27.5	(96:4)	1.80	103.3	(99:1)	1.80
99	(99:1)	2.73						
999	(99.9:0.1)	4.09						

Hydrogenation reaction:

bonds broken			bonds formed		
1	C=C	163 kcal/mol	1	C–C	88 kcal/mol
1	H–H	104 kcal/mol	2	C–H	2 x 98 kcal/mol
		267 kcal/mol			284 kcal/mol

-Overall reaction is *exothermic* -> ΔG = –17 kcal/mol, so reaction is *favorable, spontaneous.*

-To calculate equilibrium constant:

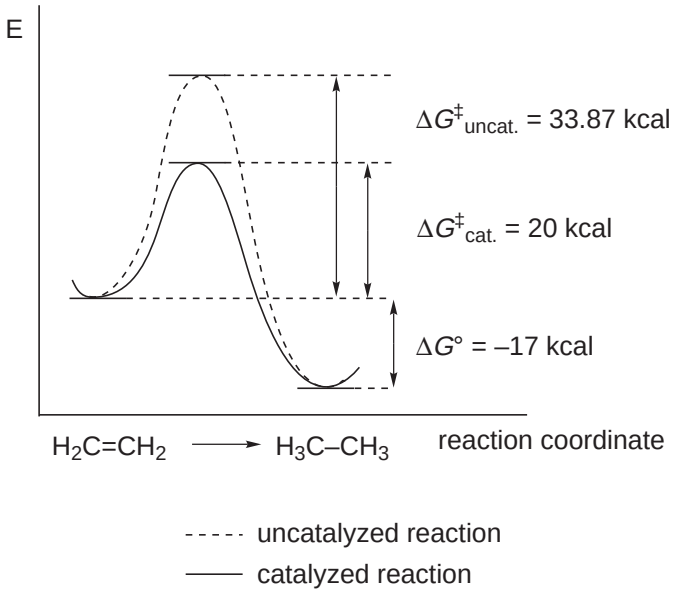
$$\ln K_{eq} = -\frac{\Delta G}{RT}$$

$$2.303 \log K_{eq} = 17 \text{ kcal} \times 1000 \text{ cal/mol} / (298 \text{ K}) \times 1.99$$
$$\log K_{eq} = 12.45$$
$$K_{eq} = 2.8 \times 10^{12}$$

- But experimentally this reaction is very slow.
- Molecule rate (experimentally) = 10^{12} molecules/sec

$$\text{mole rate} = \frac{6.023 \times 10^{23} \text{ molecules/mol}}{(10^{12} \text{ molecules/sec}) \times (60 \text{ sec/min}) \times (60 \text{ min/hour}) \times (24 \text{ hour/day}) \times (365 \text{ day/year})} = 2 \times 10^4 \text{ years}$$

i.e., 2 x 10^4 years to hydrogenate one mole of ethylene (without catalyst).



Transition State: A transition state (TS) possesses a defined geometry and charge delocalization but has no finite existence. At TS, energy usually higher and although many reactant bonds are broken or partially broken, the product bonds are not yet completely formed.

B. Transition State Theory

$$\Delta G^{\ddagger} = \Delta H^{\ddagger} - T\Delta S^{\ddagger}$$

- Free Energy of Activation ($\Delta G^{\ddagger}$)
- Enthalpy of Activation ($\Delta H^{\ddagger}$): Difference in bond energy between reactants and the transition state.
- Entropy of Activation ($-T\Delta S^{\ddagger}$): $\Delta S^{\ddagger}$ usually negative, making the change more endothermic.

From $\Delta G^{\ddagger} = \Delta H^{\ddagger} - T\Delta S^{\ddagger}$, $\Delta G^{\ddagger} = -RT \ln K^{\ddagger}$

for uncatalyzed H_2 reaction $\Delta G^{\ddagger}$ = 33.9 kcal/mol

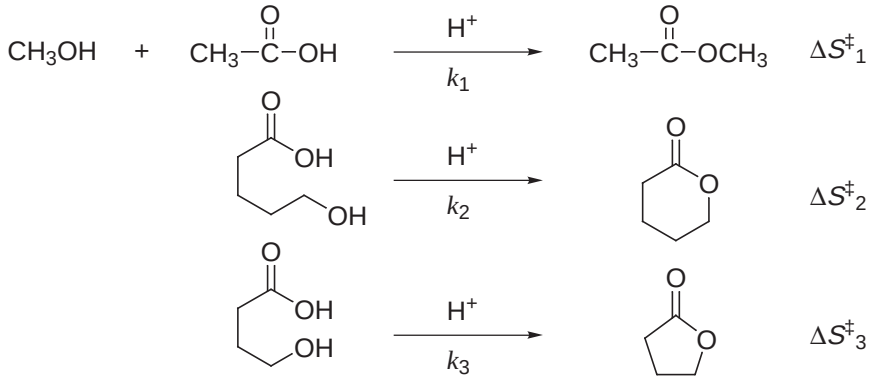
catalyzed H_2 reaction $\Delta G^{\ddagger}$ = 20 kcal/mol

and for the rate

for uncatalyzed H_2 reaction $k = 1.0 \times 10^{12}$ mol/sec

catalyzed H_2 reaction $k = 1.0 \times 10^{22}$ mol/sec

C. Intramolecular Versus Intermolecular Reactions



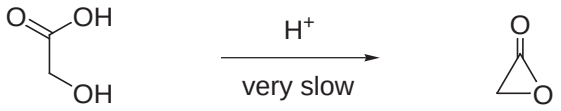
$k_3 > k_2 > k_1$

$-T\Delta S^{\ddagger}_1 > -T\Delta S^{\ddagger}_2 > -T\Delta S^{\ddagger}_3 > 0$

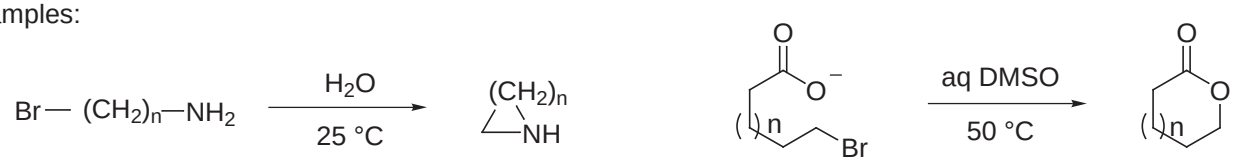
$\Delta S^{\ddagger}_1 < \Delta S^{\ddagger}_2 < \Delta S^{\ddagger}_3 < 0$

$\Rightarrow \Delta G^{\ddagger}_3 < \Delta G^{\ddagger}_2 < \Delta G^{\ddagger}_1$

- Intramolecular versus intermolecular reactions benefit from a far more favorable entropy of activation ($\Delta S^{\ddagger}$).
- In forming small rings, ring strain developing in the product decelerates the rate of reaction (large $\Delta H^{\ddagger}$) and that can offset the favorable $\Delta S^{\ddagger}$ rate acceleration.



Examples:

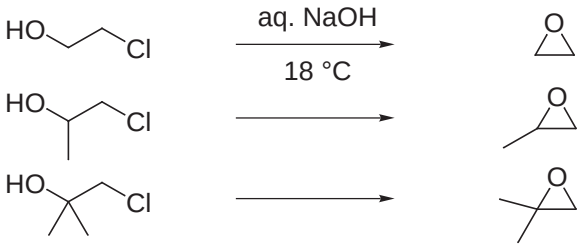


Ring size	Rel. Rate
3	70
4	1.0
5	10000
6	1000
7	2

Ring size	Rel. Rate
3	21.7
4	5.4×10^3
5	1.5×10^6
6	1.7×10^4
7	97.3
8	1.00
9	1.12
10	3.35

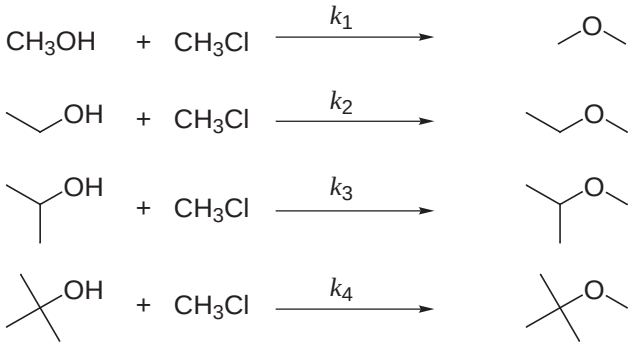
Ring size	Rel. Rate
11	8.51
12	10.6
13	32.2
14	41.9
15	45.1
16	52.0
17	51.2
18	60.4

- gem dimethyl effect



Rel. Rate
1.0
325
39000

Compare to relative rates of intermolecular S_N2 displacement where the more substituted alkoxide reacts slowest:



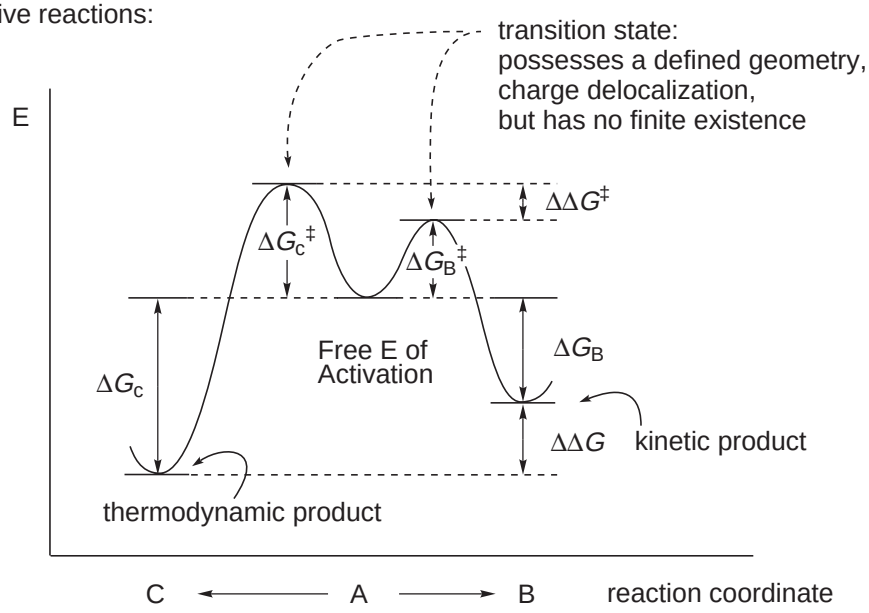
$k_1 > k_2 > k_3 > k_4$

De Tar *J. Am. Chem. Soc.* **1980**, *102*, 4505.
Winnik *Chem. Rev.* **1981**, *81*, 491.
Mandolini *J. Am. Chem. Soc.* **1978**, *100*, 550.
Illuminati *J. Am. Chem. Soc.* **1977**, *99*, 2591.
Mandolini, Illuminati *Acc. Chem. Res.* **1981**, *14*, 95.

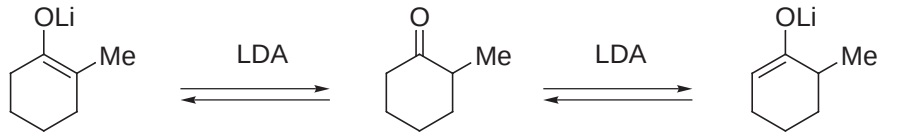
For the intramolecular case:
The reactive conformation is more favorable and populated to a greater extent in the more substituted case
⇒ One must consider both length of chain (i.e., ring size being formed) and nature of atoms in the chain (i.e., conformation, hybridization).

D. Kinetic and Thermodynamic Control

– For competitive reactions:



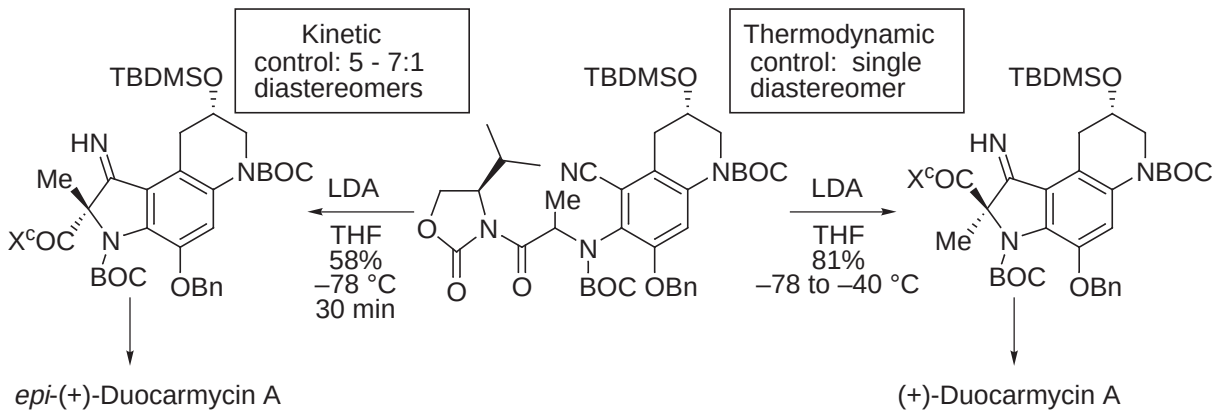
If this is an irreversible reaction, most of the reaction product will be B (kinetic product).
If this is a reversible reaction, most will be C (more stable, thermodynamic product).



thermodynamic product
more favorable ΔG

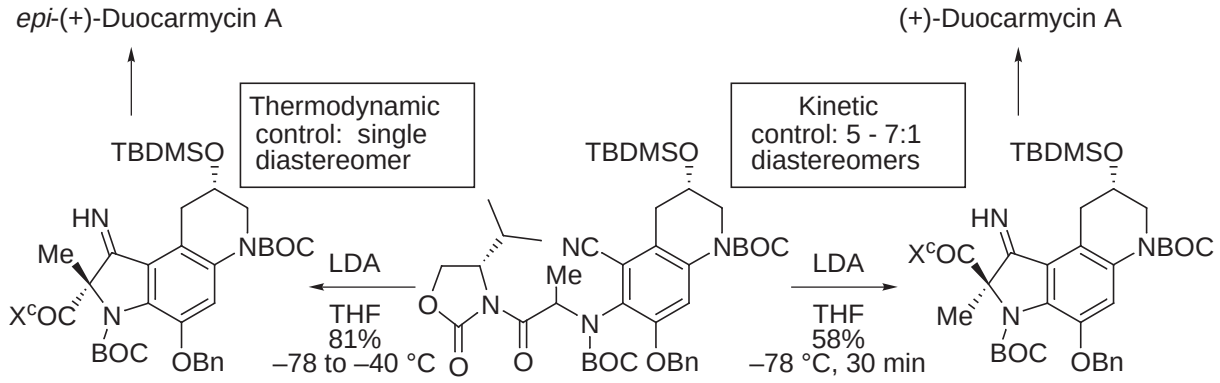
kinetic product
more favorable $\Delta G^{\ddagger}$

A beautiful example of this was observed in the kinetic versus thermodynamic asymmetric Dieckmann-like condensation illustrated below. The most stable product (lower ΔG) was observed upon conducting the reaction under equilibrating conditions for the reversible reaction while the alternative kinetic product (lower $\Delta G^{\ddagger}$) was observed when the reaction was conducted under lower temperature and nonequilibrating conditions (kinetic conditions).

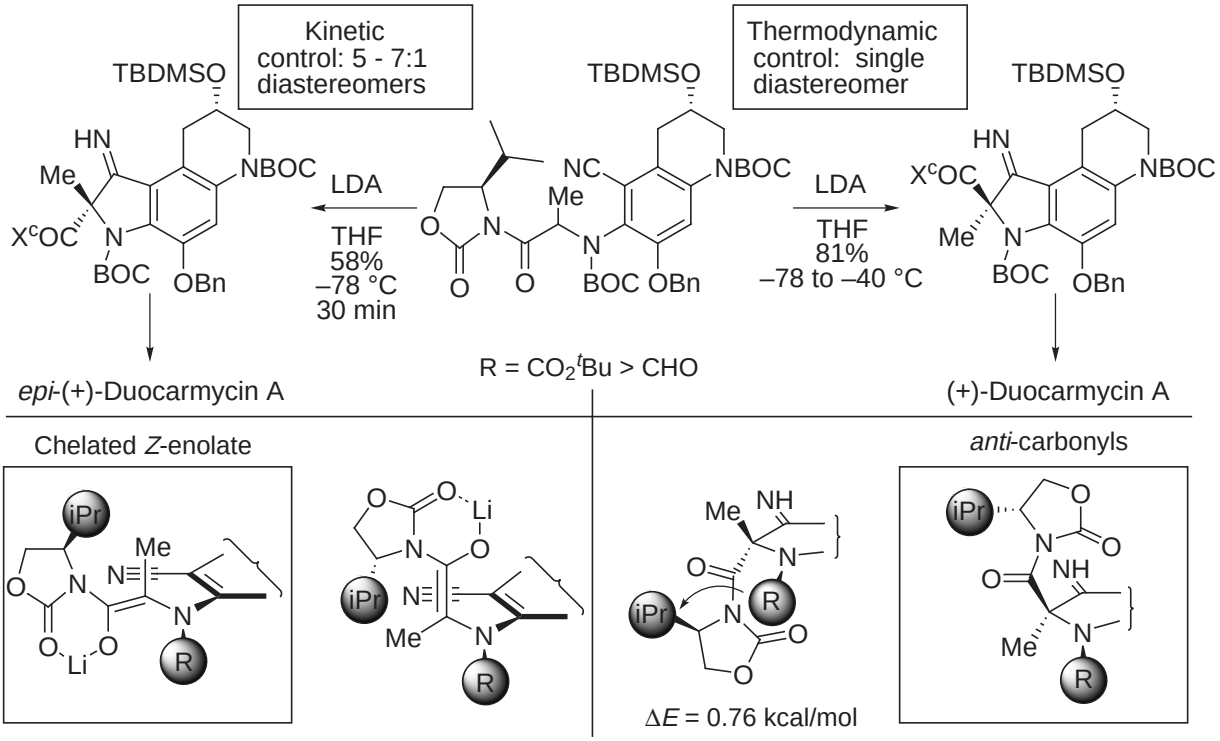


epi-(+)-Duocarmycin A

(+)-Duocarmycin A



Divergent Control of C6-Stereochemistry



Boger *J. Am. Chem. Soc*. **1997**, *119*, 311.

E. Hammond Postulate

The geometry of the transition state for a step most closely resembles the side (i.e., reactant or product) to which it is closer in energy.

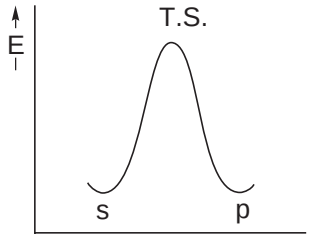
Transition state can not be studied experimentally – has zero lifetime (transient species)

→ information obtained indirectly

⇒ Hammond postulate

Examples:

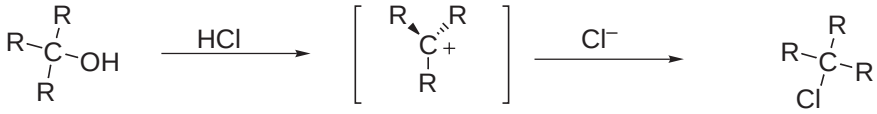
1) Thermoneutral reactions:

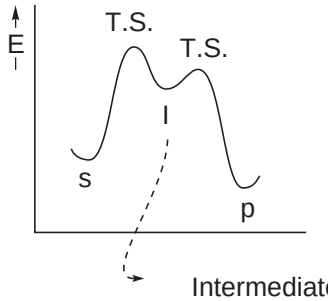


Thermoneutral reaction –
transition state resembles both
starting material and product equally

2) For reactions which proceed through an intermediate: solvolysis of tertiary alcohol

X: discrete intermediate





G. A. Olah received the 1994 Nobel Prize in Chemistry for his contributions to carbocation chemistry.

Resemble the geometry of the carbocation intermediate and not that of the reactant (alcohol) or product (alkyl chloride).

Intermediate (for this reaction it will be C^+ so T.S. $\Rightarrow$ I)

Notes
a. 20 kcal/mol energy available at 25 °C for free energy of activation.
b. Increase reaction temperature, increase the rate of reaction.
c. Decrease reaction temperature, decrease the rate of reaction, but increase the selectivity of the reaction.

Hammond *J. Am. Chem. Soc.* **1955**, *77*, 334.
Casin *J. Chem. Ed.* **1975**, 52, 76.

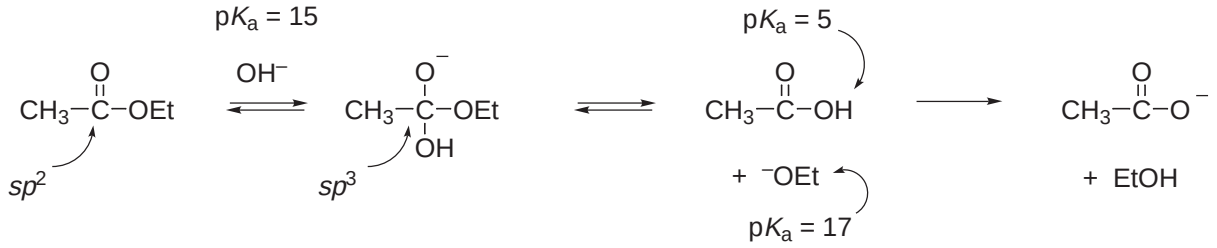
F. Principle of Microscopic Reversibility

The forward or reverse reactions, run under identical conditions, must proceed by the same mechanism
i.e., if forward reaction proceeds via intermediate X

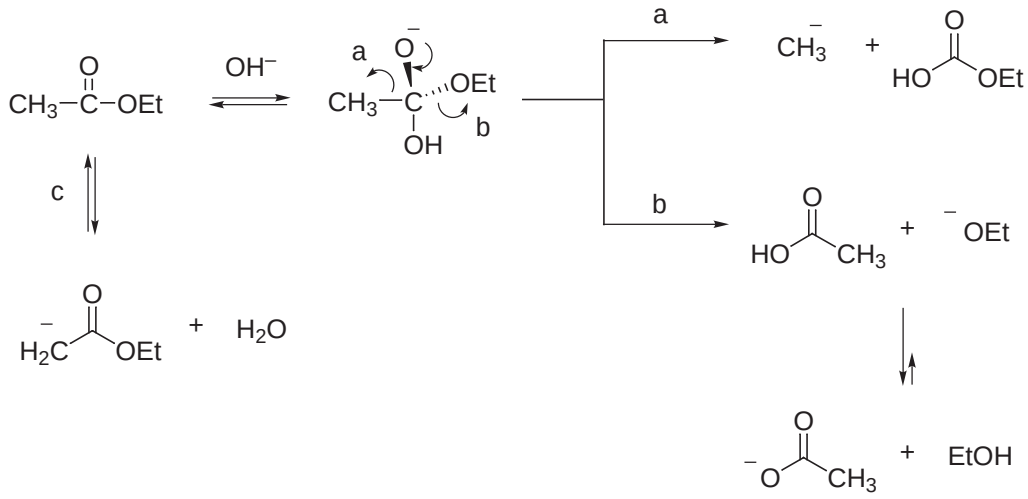
then reverse reaction also goes through X.

III. Reaction Mechanisms and Conformational Effects on Reactivity

A. Ester Hydrolysis

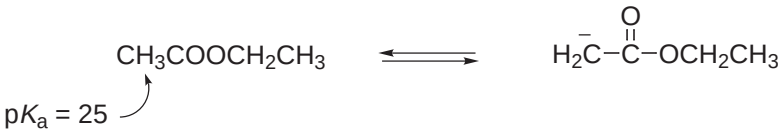


Reaction driven to completion by final, irreversible step (compare pK_a = 17 to pK_a = 5).



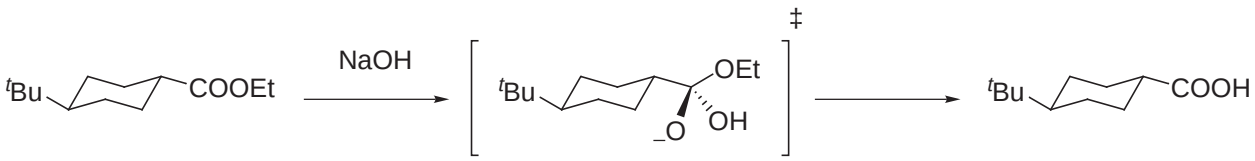
- So, possible competing reaction is α-H removal, but pK_a difference means equilibrium strongly favors ester and OH^-, i.e.;

- To deprotonate an ester, must use a strong base which is non-nucleophilic, such as ^{t}BuOK or LDA.



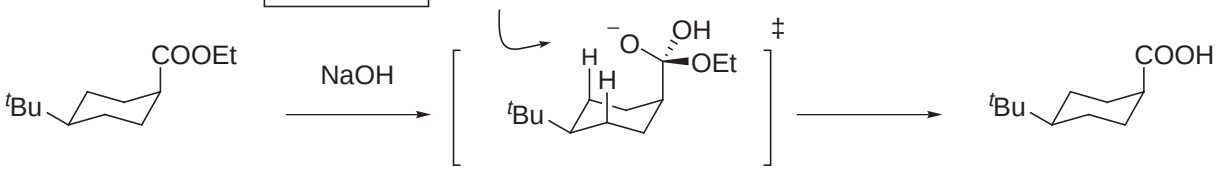
1. ^{t}BuOK (pK_a of ^{t}BuOH = 19) → generates low concentration of anion, and a significant amount of ester always present
   ⇒ self (Claisen) condensation
2. LDA (pK_a of ^{i}Pr$_2$NH = 36) → generates a high concentration of enolate and thus is a good base to carry out stoichiometric alkylation of ester

1. Kinetics of Ester Hydrolysis (Stereochemistry and Rates of Reactions)



Steric Effect

no way to avoid a severe ^{t}Bu-like 1,3-diaxial interaction



A value = 1.2 kcal

A value = 2.3 kcal

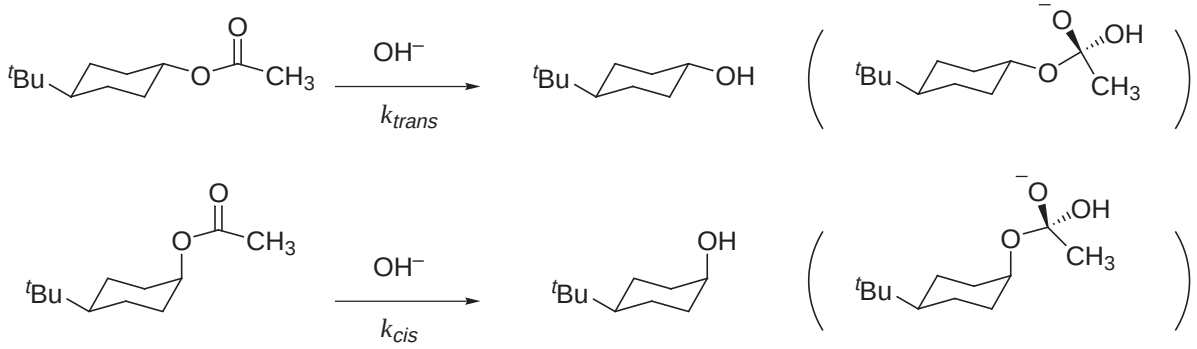
$$\frac{k_{trans}}{k_{cis}} = 19.8 \rightarrow 95:5$$

The rate determining step for ester hydrolysis is the formation of tetrahedral intermediate and the ratio of k_{trans}/k_{cis} >> 1.

Eliel *J. Am. Chem. Soc.* **1961**, *83*, 2351.

- Difference in rates much greater than expected if simply considering the difference in either the product or reactant A values.
- Reaction of axial ester decelerated due to more severe developing 1,3-diaxial interactions in transition state (i.e., an axial ^{t}Bu-like group).

2. Same effect is observed, but to a lesser extent with acetate hydrolysis



A value = 0.7 kcal/mol

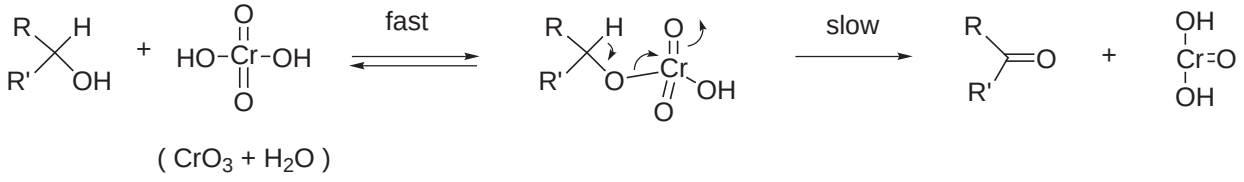
$$\frac{k_{trans}}{k_{cis}} = 6.65$$

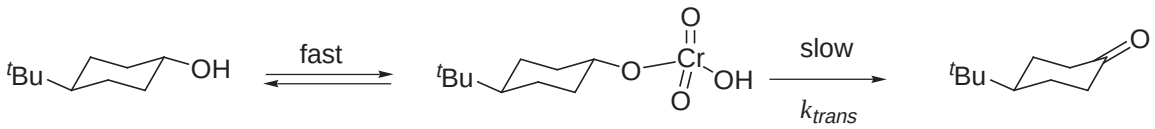
effect is smaller because of the more remote distance of the steric interactions

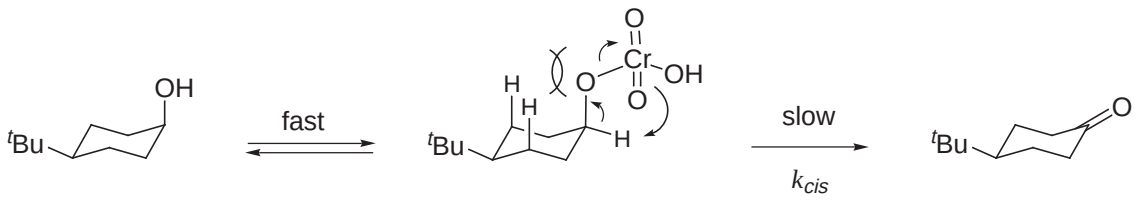
Similarly, the rates of acetylation are $k_{trans}/k_{cis} = 3.7$

Eliel *J. Am. Chem. Soc.* **1966**, *88*, 3334.

B. Alcohol Oxidations







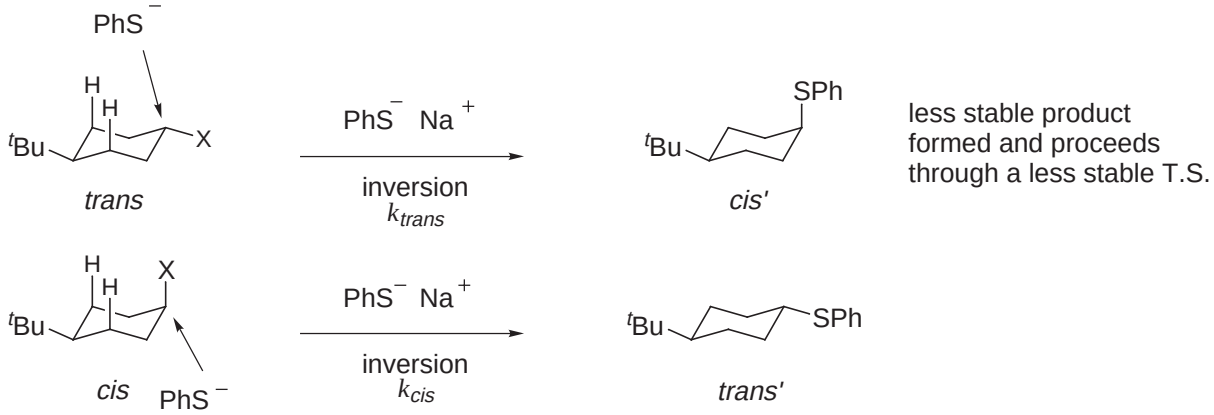
$$\frac{k_{cis}}{k_{trans}} = 4$$

The rate determining step for the alcohol oxidation is break down of the chromate ester with cleavage of C–H bond and O–Cr bond.

Destabilizing 1,3-diaxial interactions in *cis* chromate ester accelerate its breakdown to the ketone (would be slower if the slow step for the reaction were formation of chromate ester).

Eliel *J. Am. Chem. Soc.* **1966**, *88*, 3327.

C. S_N2 Reactions



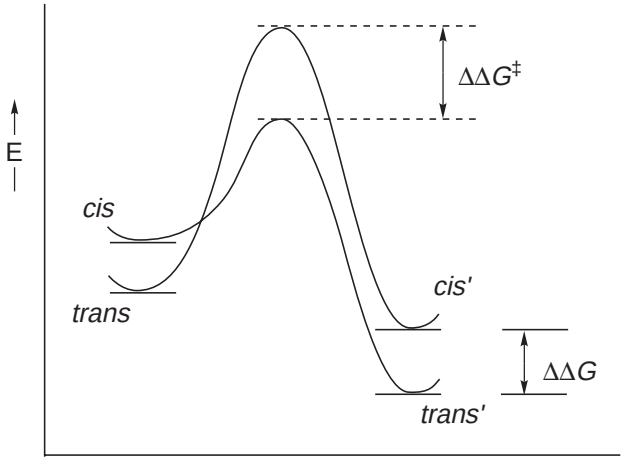
less stable product formed and proceeds through a less stable T.S.

- The free energy of activation (E_a, or $\Delta G^{\ddagger}$) for reaction of the *trans* isomer is higher due to steric interactions felt in the transition state (interactions of incoming nucleophile with axial H's).

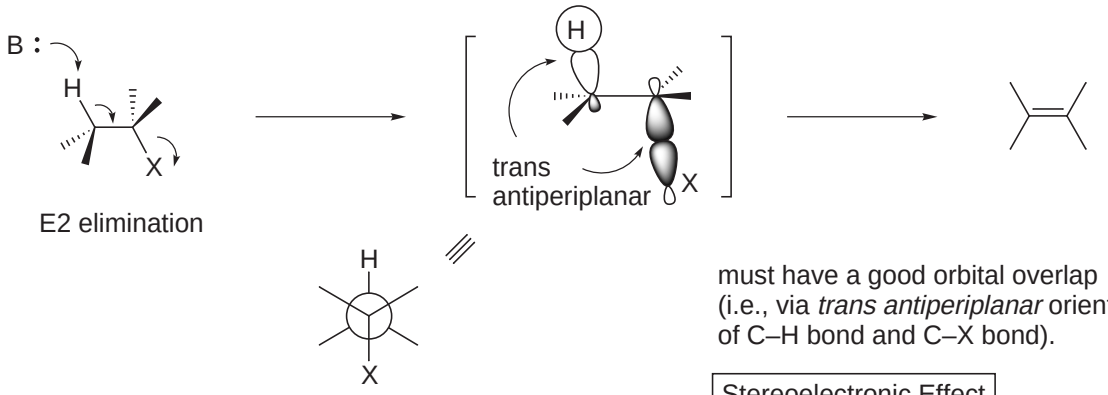
  $\rightarrow$ $k_{cis} > k_{trans}$

  $\Delta\Delta G^{\ddagger}$ greater than $\Delta\Delta G$ of products.

- The reaction of the *trans* isomer is kinetically slower and thermodynamically less favorable.



D. Elimination Reactions

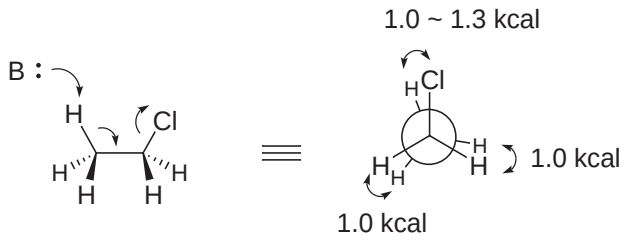


E2 elimination

must have a good orbital overlap (i.e., via *trans antiperiplanar* orientation of C–H bond and C–X bond).

Stereoelectronic Effect

- Alternatively, if dihedral angle = 0° (i.e., eclipsed X and H), elimination can take place (orbital overlap good).



eclipsed conformation is 3.0–3.3 kcal/mol higher in E, so elimination takes place mainly through *trans periplanar* arrangement.

- Alternate mechanisms also possible:

E1 mechanism

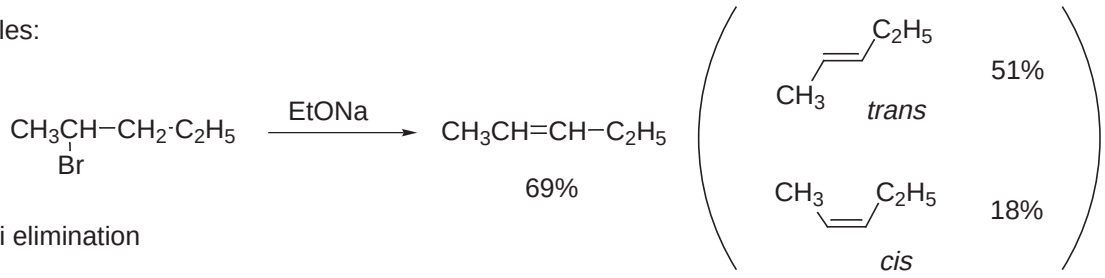
via free carbocation

large groups (A,E) trans

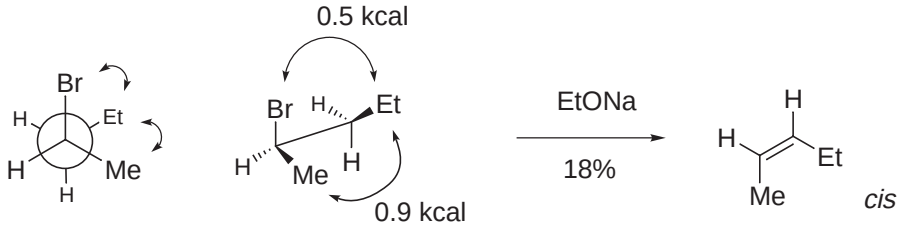
E1cB mechanism

Acyclic Substrate

– Examples:

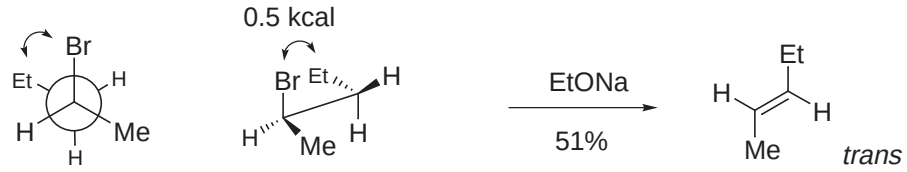


Anti elimination



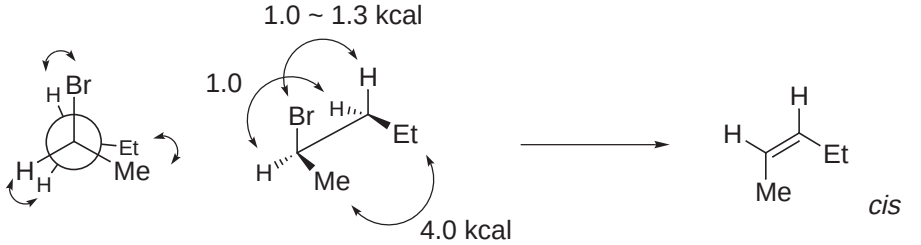
ΔE = 0.9 kcal

trans is more stable than *cis* (1.0 kcal/mol)

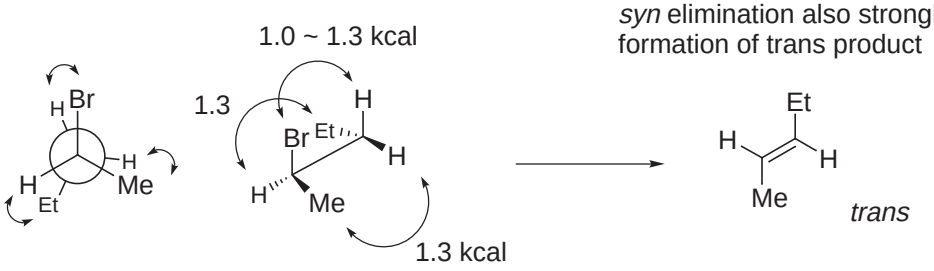


– For other possible mechanisms:

Syn elimination

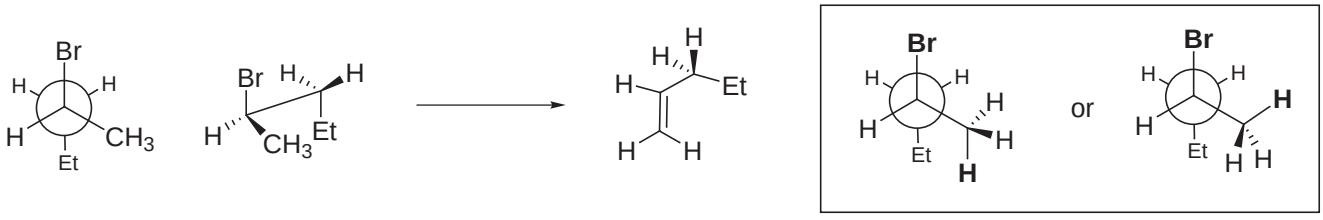


syn elimination also strongly favors formation of trans product



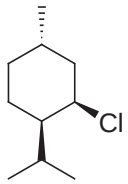
Both are very much destablized relative to *anti*-elimination T.S. / conformations.
Neither contribute to ground state conformation of bromide at room temperature.

And, there is another product formed:

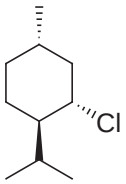


Cyclic Substrate

Consider E2 elimination of

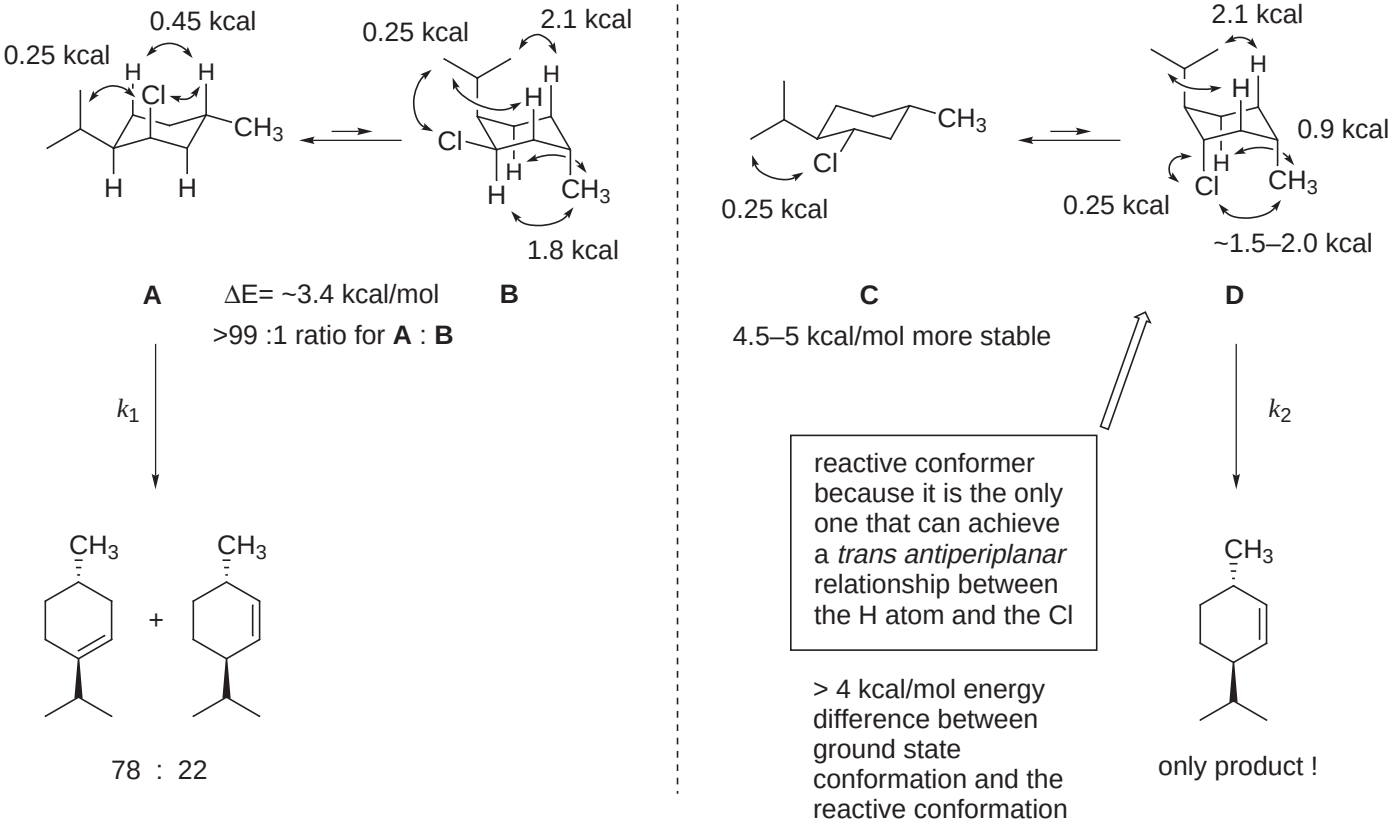


neomenthyl chloride



menthyl chloride

Look at all conformations of each:



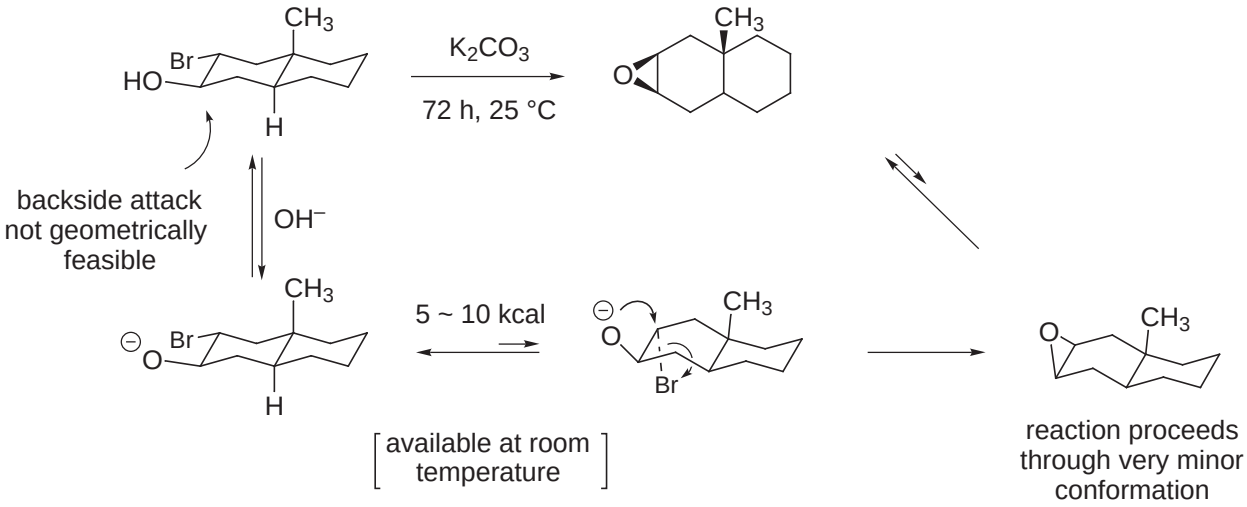
The reaction of the neomenthyl chloride is much faster (k_1/k_2 = 193:1)

From **D** (menthyl chloride) – only one product is possible

Curtin–Hammett principle : Ground state conformation need not be decisive in determining product of a reaction.

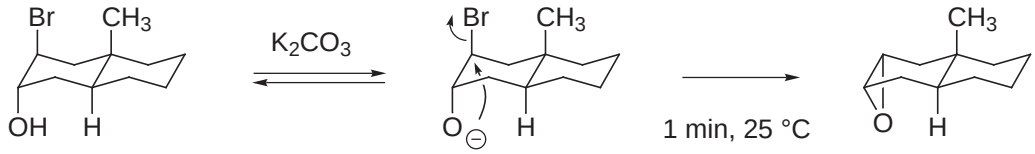
E. Epoxidation by Intramolecular Closure of Halohydrins

– Must involve backside displacement → geomerical constraints !



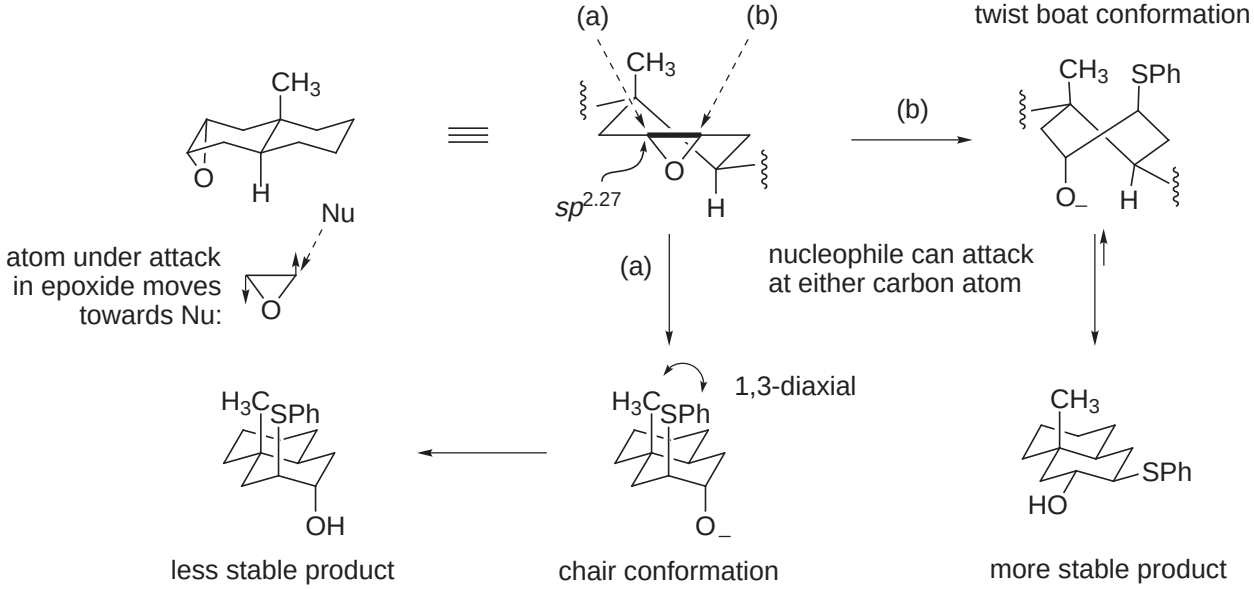
Again, ground state conformation of reactant is not a determinant in reaction product (Curtin–Hammett principle).

– Another example:



reaction much faster and proceeds from a ground state conformation

F. Epoxide Openings (S_N2)



less stable product | chair conformation | more stable product

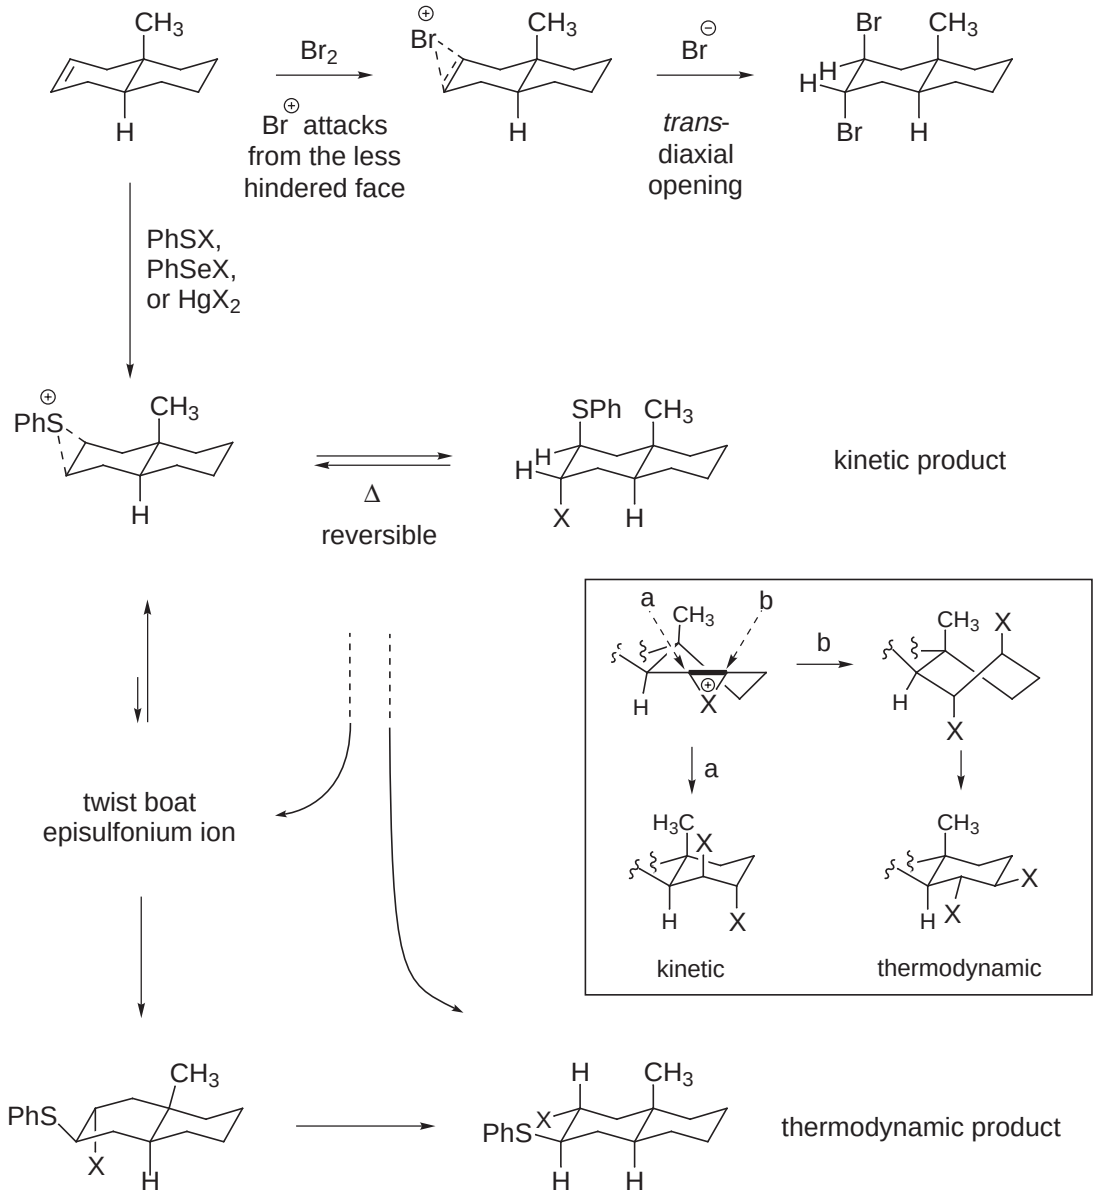
This is the only product formed!

⟹ Product ratio dependent on E_a (i.e., relative energy of two T.S.), route (a) proceeding through chair conformation and destabilizing 1,3-diaxial interaction is of lower energy than route (b) proceeding through twist boat T.S.

- Conformational effects determine regioselectivity

G. Electrophilic Additions to Olefins

Follows same principles

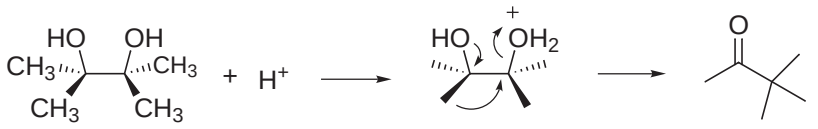


- Conformational effects control regioselectivity and stereochemistry

  But, it is not always possible to obtain the thermodynamic product
  ⇒ must have the 20–30 kcal/mol of energy required and a mechanism to reverse the reaction.

H. Rearrangement Reactions

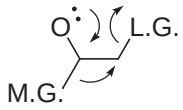
pinacol → pinacolone rearrangement



pinacolone

– Prototype of rearrangement:

heteroatom:



migrating group

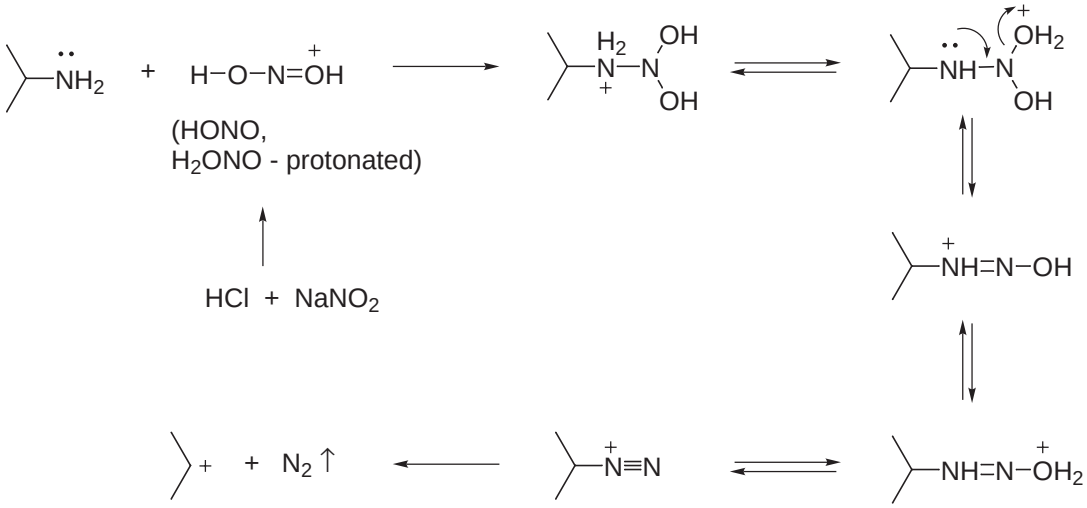
leaving group

$-OH_2^+$

$-OSO_2R$

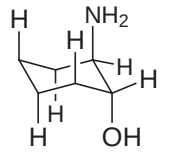
$-N_2^+$ diazonium ion

This process is conformationally dependent!

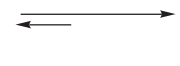


The course of rearrangement is conformationally dependent:

A value of NH_2/NH_3^+ (1.8–1.4 kcal)



A value of OH
(0.7 kcal)



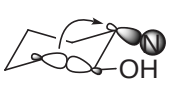
ΔE = 1.6 ~ 2.2 kcal

gauche (0.35–0.9 kcal)

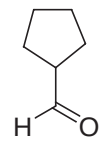
HONO

Stereoelectronic Effect

backside attack

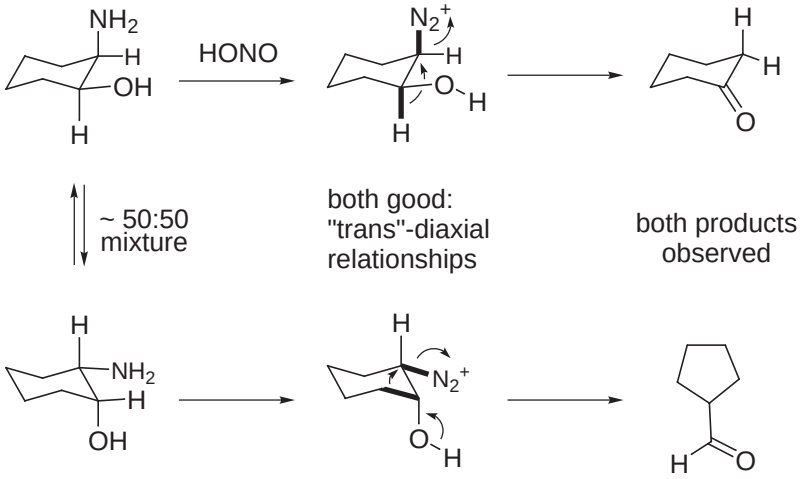


trans periplanar arrangement



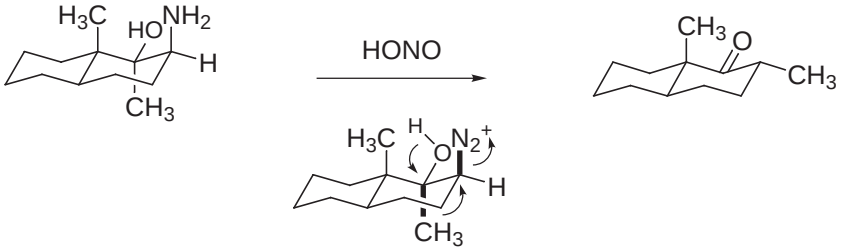
only product observed

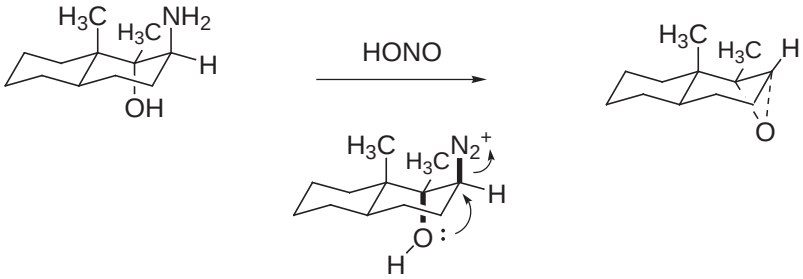
Compare to:

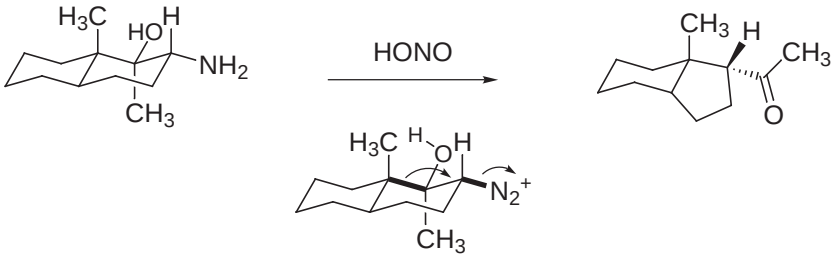


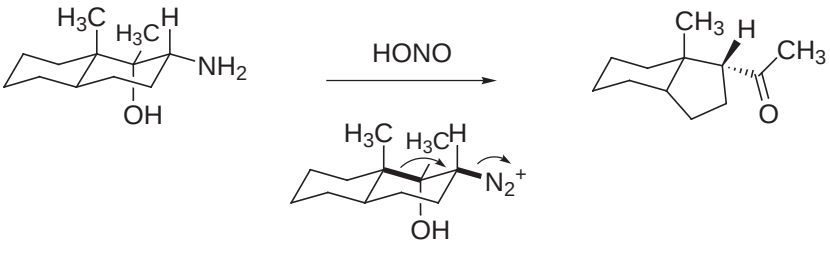
Stereoelectronic effects dominate the control of regioselectivity

Explain the following results:

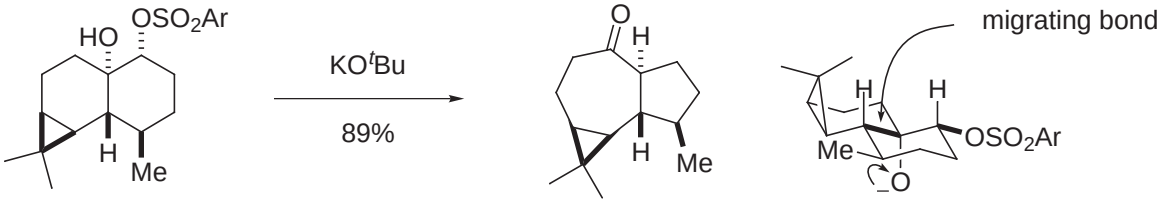




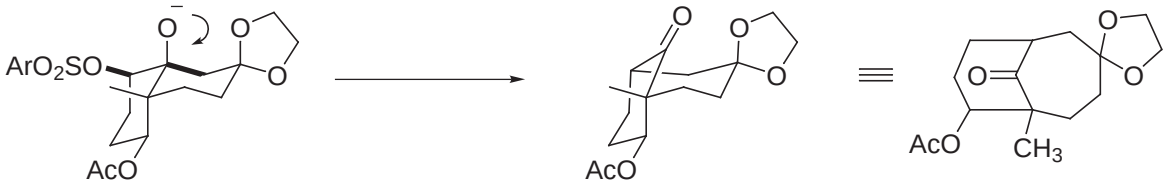




- Additional examples



Büchi *J. Am. Chem. Soc.* **1966**, *88*, 4113.



Heathcock *J. Am. Chem. Soc.* **1982**, *104,* 1907.

I. Pericyclic Reactions

1. Conservation of Orbital Symmetry, FMO Analysis

- Concerted reactions where there is a single transition state and no intermediates proceed through cyclic transition states.
- Cyclic transition state corresponds to an allowed arrangement of participating orbitals that can maintain a bonding interaction between the reaction components throughout the course of the reaction. This dictates features of relative reactivity, regioselectivity, and diastereoselectivity.
- This also established and formalized the viability of utilizing Frontier Molecular Orbitals (FMO) composed of the Highest Occupied Molecular Orbital (HOMO) and Lowest Unoccupied Molecular Orbital (LUMO) to analyze pericyclic reactions.

Woodward, Hoffmann *The Conservation of Orbital Symmetry,* Academic: New York, 1970.
J. Am. Chem. Soc. **1965**, *87*, 395.

Fukui *Acc. Chem. Res.* **1971**, *4*, 57; *Angew. Chem., Int. Ed. Eng.* **1982**, *21*, 801.

Encouraged by E. J. Corey, Hoffmann began examining mechanistic problems in organic chemistry and, as a junior fellow at Harvard, entered into a collaboration with R. B. Woodward that combined his insights in MO theory with Woodward's knowledge of experimental pericyclic reactions. This led to five papers in 1965 before he was 30 years old, that were the foundation of what we now refer to as the **Woodward-Hoffmann rules**.

R. Hoffmann received the 1981 Nobel Prize in Chemistry for the launch and development of the concept of orbital symmetry conservation.

K. Fukui received the 1981 Nobel Prize in Chemistry for his Frontier Orbital theory of chemical reactivity.

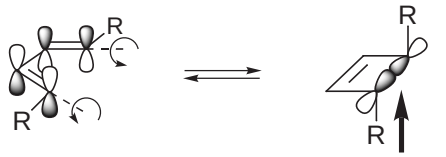
This followed and was not included in the 1965 Nobel Prize in Chemistry awarded to R. B. Woodward for his contributions to the "art of organic synthesis".

2. Electrocyclic Reactions

- This is composed of a series of reactions in which a ring closure occurs with formation of a single bond at the ends of a linear, conjugated system of π electrons and the corresponding reverse reaction with ring opening.

System	π electrons	Thermal Reaction Ground State (HOMO)	hν Reaction Excited State (LUMO)
	4 π e^-	conrotatory	disrotatory
	6 π e^-	disrotatory	conrotatory
	8 π e^-	conrotatory	disrotatory
	2 π e^-	disrotatory	conrotatory
	4 π e^-	conrotatory	disrotatory
	4 π e^-	conrotatory	disrotatory
	6 π e^-	disrotatory	conrotatory

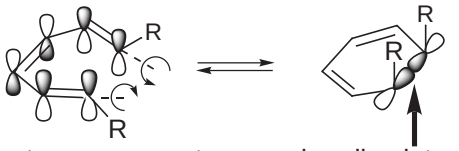
4 π e^- thermal reaction (ground state, HOMO)



conrotatory movement ⟶ bonding interaction

- Stereochemistry dictated by orbital symmetry allowed reaction course

6 π e^- thermal reaction (ground state, HOMO)



disroratory movement ⟶ bonding interaction

- Generalization:

No. of π electrons	Thermal	hν
4n π electrons (n = 0,1,...)	conrotatory	disrotatory
4n + 2 π electrons (n = 0,1,...)	disrotatory	conrotatory

3. Cycloadditions and Cycloreversions

- These are discussed in terms of suprafacial or antarafacial addition to the ends of a π system.

Suprafacial  Antarafacial 
- Generalization:

Total π electrons	Allowed in Ground State	Allowed in Excited State
4n	$m_s + n_a$	$m_s + n_s$
	$m_a + n_s$	$m_a + n_a$
4n + 2	$m_s + n_s$	$m_s + n_a$
	$m_a + n_a$	$m_a + n_s$

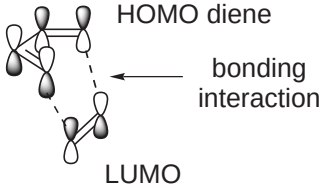
- Notations

orbital type (π, σ, ω) ⟹ $\pi 2_s$ ⟸ suprafacial (s) or antarafacial (a)

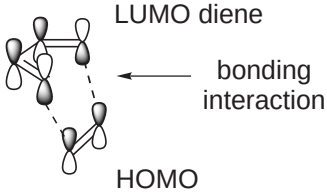
⇧ number of e^-

- Diels-Alder Reaction (6π e^-), Ground State Thermal Reaction

Normal Diels-Alder Reaction



Inverse Electron Demand Diels-Alder Reaction

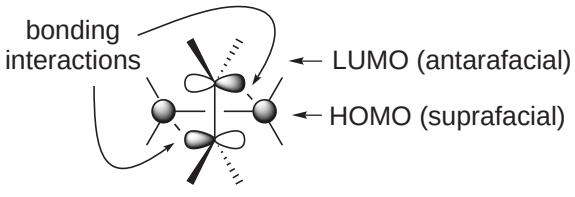


$[\pi 4_s + \pi 2_s]$ cycloaddition

- Suprafacial with respect to both reacting components and this defines the orientation with which the two reactants approach, boat transition state.
- The FMO analysis may also be used to predict relative rates, regioselectivity, and diastereoselectivity (*endo* effect) and we will discuss this in detail along with the Diels-Alder reaction.

- [2 + 2] Cycloaddition (4π e^-)

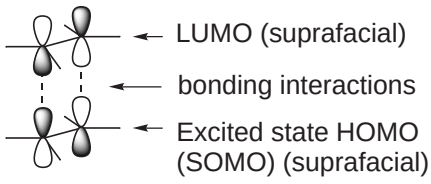
Ground State (thermal)



$[\pi 2_a + \pi 2_s]$ cycloaddition

- Antarafacial with respect to one olefin and suprafacial with respect to the second, dicates perpendicular approach to permit bonding.

Excited State (hν)



$[\pi 2_s + \pi 2_s]$ cycloaddition

- Suprafacial with respect to both olefins.

4. Sigmatropic Rearrangements

- Class of reactions characterized by migration of an allylic group from one end of a π system to the other.
- Generalization:

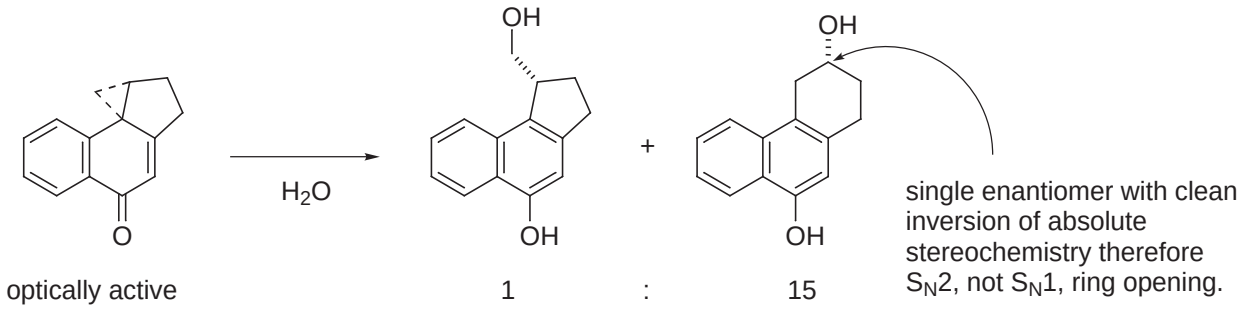
Total π electrons	Ground State	Excited State
4n	antara - supra supra - antara	antara - supra supra - antara
4n + 2	supra - supra antara - antara	antara - supra supra - antara

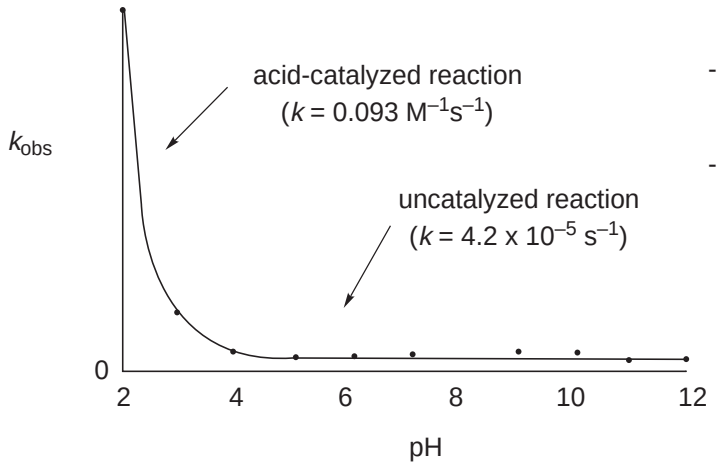
- These include a wide range of rearrangements including [1,3]-, [1,5]-, [1,7]-, [3,3]-, and [2,3]-sigmatropic reactions which we will discuss in detail.

J. Subtle Conformational and Stereoelectronic Effects on Reactivity and Reaction Regioselectivity

1. Kinetics, Stereochemistry, and Reaction Mechanisms

- Two of the cornerstones of defining a mechanism rest with the establishment of the stereochemistry of the reaction in conjunction with kinetic studies of the reaction.
- For example, for a reaction that might entail acid or base catalysis, it is common to examine the pH rate profile.



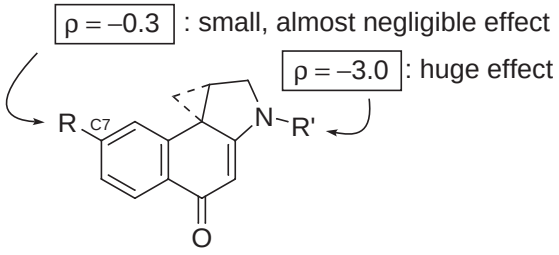


- Below pH 4, H^+ catalyzed reaction dominates.
- Above pH 4 (pH 4–12), the uncatalyzed direct S_N2 addition reaction dominates.

Boger *J. Org. Chem.* **1998**, *63*, 8004.

2. Substituent Effects

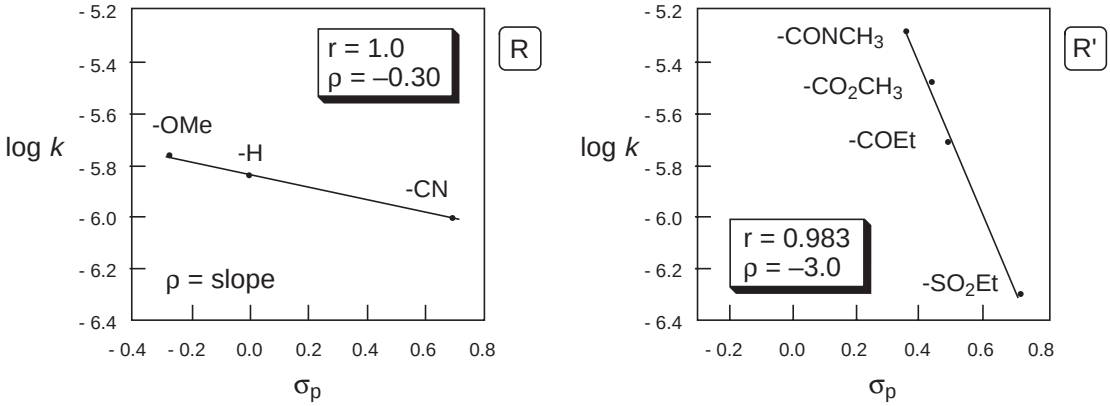
- These can be quantitated using a Hammett treatment and can provide insights into reaction mechanisms.



- C7 substituents (R) have little effect on reactivity
- N substituent (R') has a pronounced effect on reactivity and even subtle perturbations will change reactivity greatly ($-SO_2R \rightarrow -CO_2R$, 10 x)

ρ values are characterized in a log scale

- The negative ρ value indicates δ^+ charge buildup in the rate-determining step of the reaction.

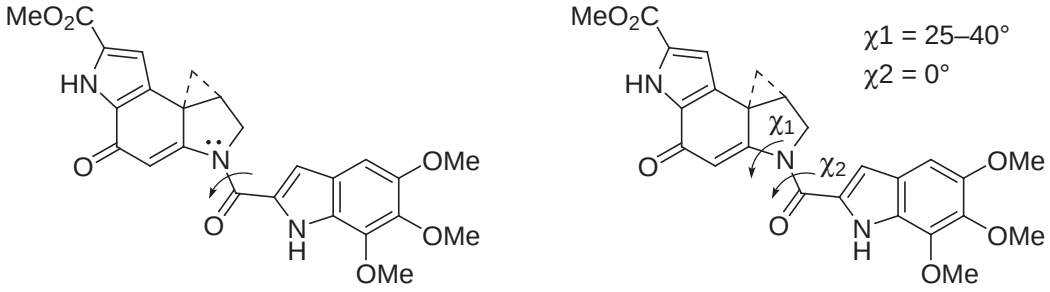


Boger *J. Am. Chem. Soc.* **1994**, *116*, 5523.
J. Org. Chem. **1996**, *61*, 1710 and 4894.

3. Structure versus Reactivity and Reaction Regioselectivity

- Structure can have a pronounced effect on reactivity and reaction regioselectivity.
One nice example of this can be illustrated with a series of analogues related to CC-1065 and the duocarmycins which are potent antitumor antibiotics that derive their biological properties from a sequence-selective DNA alkylation reaction. The reactivity changes that one sees as a consequence of the loss of the vinylogous amide stabilization are related to the source of DNA alkylation catalysis.

Binding-induced conformational change: shape-selective catalysis

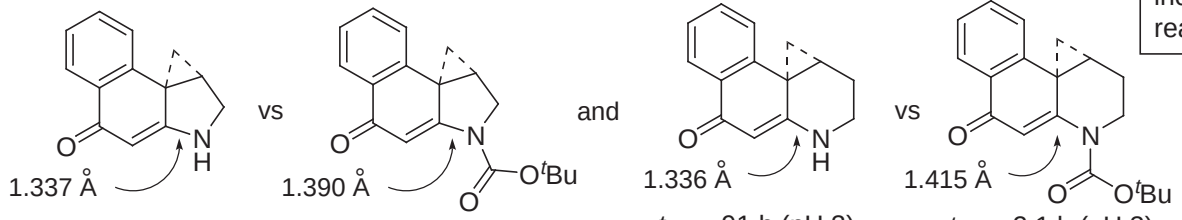


- DNA bound agent adopts helical conformation, twist adjusted at linking amide.
  - DNA bound agent maintains full amide. ($\chi 2 = 0°$)
  - Vinylogous amide stabilization diminished. ($\chi 1 = 25–40°$)
  - Cyclohexadienone structure destabilized.
- **Shape-dependent catalysis**: Preferential activation in AT-rich minor groove.
Binding induced twist greatest in the narrower, deeper AT-rich minor groove.
- **Shape-selective recognition**: Preferential binding in AT-rich minor groove.

Boger *J. Am. Chem. Soc.* **1997**, *119*, 4977 and 4987.
Boger, Garbaccio *Bioorg. Med. Chem.* **1997**, *5*, 233.

- *N*-Acylation and its effect on vinylogous amide and cyclopropane conjugation.

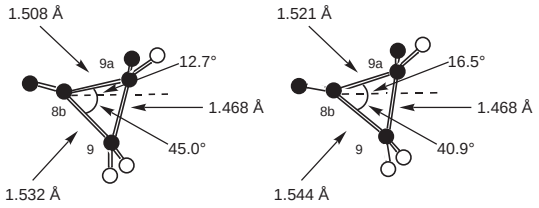
(+)-CBI vs (+)-*N*-BOC-CBI and (–)-CBQ vs (–)-*N*-BOC-CBQ



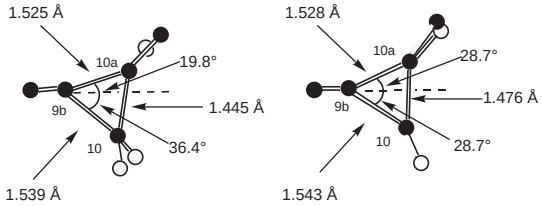
ca. 10–50 x increase in reactivity

$t_{1/2}$ = 920 h (pH 3) | $t_{1/2}$ = 133 h (pH 3) | $t_{1/2}$ = 91 h (pH 3), $t_{1/2}$ = stable (pH 7) | $t_{1/2}$ = 2.1 h (pH 3), $t_{1/2}$ = 544 h (pH 7)

X-ray

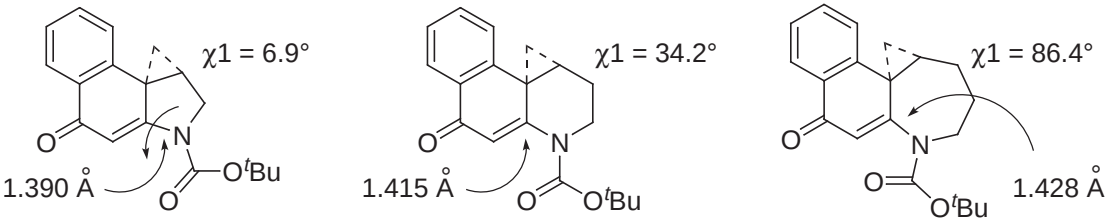


X-ray



- *N*-acylation decreases the cross-conjugated vinylogous amide conjugation, increases the cyclopropane conjugation and bond lengths, and increases cyclopropane reactiviity. This can be observed in the corresponding X-ray crystal structures.

- Amide twist effect on the vinylogous amide and cyclopropane conjugation.



H^+ catalyzed reaction → $t_{1/2}$ = 133 h (pH 3) | $t_{1/2}$ = 2.1 h (pH 3) | $t_{1/2}$ = 0.03 h (pH 3)

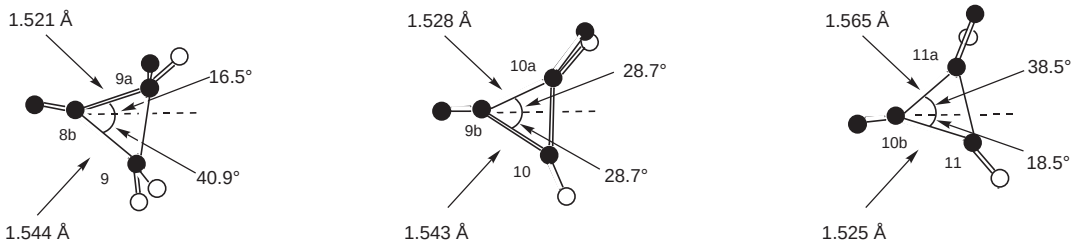
Uncatalyzed reaction → $t_{1/2}$ = stable (pH 7) | $t_{1/2}$ = 544 h (pH 3) | $t_{1/2}$ = 2.1 h (pH 7)

and rates

- Decreases vinylogous amide cross-conjugation
- Increases cyclopropane conjugation (bond lengths)
- Increases cyclopropane reactivity

10^4 x increase in reactivity

X-ray



regioselectivity: > 20 : 1 | 3 : 2 | < 1 : 20

- Note the change in solvolysis regioselectivity where the stereoelectronically aligned cyclopropane bond is the bond which is cleaved. The stereoelectronically aligned bond is that which is positioned to best overlap with the developing π-system of the product phenol.

complete reversal of reaction regioselectivity

- In each case, the ring expansion occurred with generation of a single enantiomer by a S_N2 mechanism.

Boger *J. Org. Chem.* **1997**, *62*, 5849; *J. Am. Chem. Soc.* **1997**, *119*, 4977.

K. Methods for the Synthesis of Optically Active Materials

Morrison *Asymmetric Syntheses*, Academic: New York, 1983; Vol. 1–5.

Note:
A summary of approaches which will be highlighted throughout the following material.

1. Partial Synthesis

- From readily available, naturally-derived optically active materials, examples include

a. Progesterone from sapogenin diosgenin.

b. Synthetic penicillins from the fermentation product 6-aminopenicillanic acid (6-APA).

c. Vitamin D_3 (1-hydroxycholecalciferol) from cholesterol.

2. Resolution

a. Diastereomeric salts and selective crystallization.

b. Diastereomeric derivatization and chromatography or selective crystallization.

c. Direct chromatographic resolution of enantiomers on an optically active stationary support.

d. Enzymatic resolution.

e. Kinetic resolution with selective production of desired enantiomer or selective consumption of undesired enantiomer.

Advantage: Both enantiomers are made available.

Disadvantage: 1/2 of the material is wasted if only one enantiomer is desired.
Ambiguous assignment of absolute configuration.

See: Jacques, Collet, Wilen *Enantiomers, Racemates, and Resolutions*, Wiley: New York, 1981.

3. Synthesis from Chiral Pool

- Readily available, abundant or naturally occurring starting materials.

a. Carbohydrates

b. Amino acids

c. α-Hydroxy carboxylic acids

d. Terpenes

e. Readily available, abundant natural products

O. Wallach, a colleague and collaborator of A. Kekule, received the 1910 Nobel Prize in Chemistry for his work on essential oils that converted the field of natural products from a disorganized collection of confusing observations into a complete, organized and integrated field. He established the isoprene rule.

4. Asymmetric Synthesis

a. Optically active reagent (Stoichiometric)

b. Optically active chiral auxiliary incorporated into substrate (Stoichiometric)

c. Optically active catalyst (Catalytic)

See: Koskinen *Asymmetric Synthesis of Natural Products*; Wiley: New York, 1993.
Gawley, Aube *Principles of Asymmetric Synthesis*; Elsevier: Amsterdam, 1996.

5. Microbial, Enzymatic, or Catalytic Antibody Transformation

See: Wong, Whitesides *Enzymes in Synthetic Organic Chemistry*; Pergamon: Oxford, 1994.

IV. Oxidation Reactions

A. Epoxidation Reactions: Oxidation of Carbon-Carbon Double Bonds

Comprehensive Org. Syn.; Vol. 1, 819; Vol. 7, pp. 357 and 390 (asymmetric).

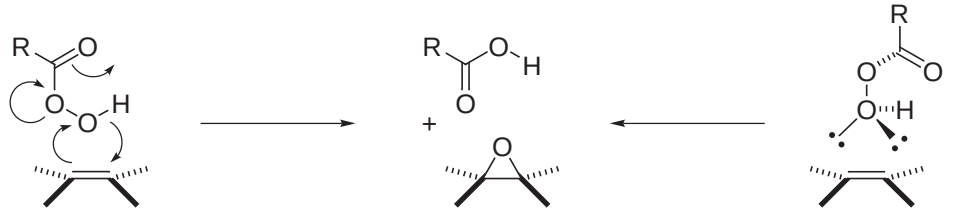
1. Peracid Reactivity

Rate increases: R = CH_3 < C_6H_5 < *m*-ClC_6H_4 < H < *p*-$NO_2C_6H_4$ <  < CF_3

pK_a of acid (RCO_2H):	4.8	4.2	3.9	3.8	3.4	2.9	0

The lower the pK_a, the greater the reactivity (i.e., the better the leaving group).

2. Mechanism



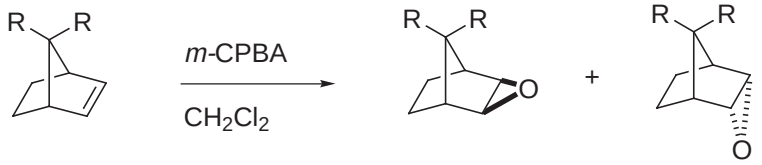
Butterfly mechanism
(usual representation)
Bartlett *Rec. Chem. Prog.* **1950**, *11*, 47.

Refined representation:
trans antiperiplanar arrangement of O-O bond and reacting alkene, n-π^* stabilization by reacting lone pair in plane.

The synchronicity of epoxide C-O bond formation and an overall transition state structure postulated using *ab initio* calculations and experimental kinetic isotope effects.
Singleton, Houk *J. Am. Chem. Soc.* **1997**, *119*, 3385.

3. Stereochemistry

a. Stereochemistry of olefin is maintained: diastereospecific.
b. Reaction rate is insensitive to solvent polarity implying concerted mechanism without intermediacy of ionic intermediates.
c. Less hindered face of olefin is epoxidized.

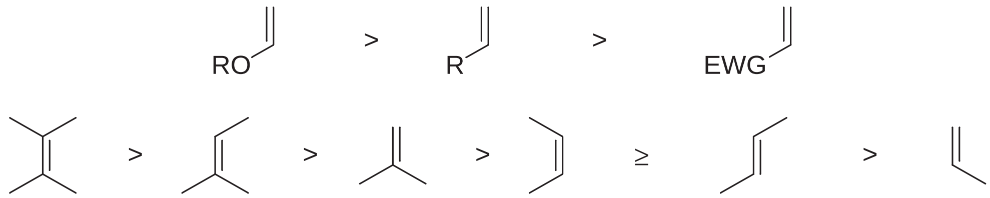


R = H	20 min, 25 °C	99%	1%
R = CH_3	24 h, 25 °C	< 10%	90%

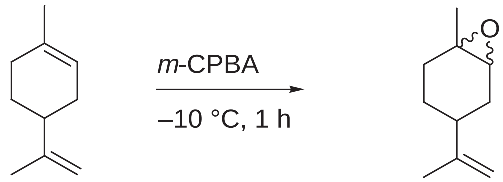
Brown *J. Am. Chem. Soc.* **1970**, *92*, 6914.

4. Chemoselectivity

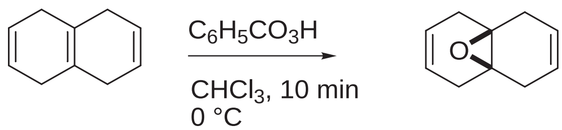
– Electrophilic reagent: most nucleophilic C=C reacts fastest.

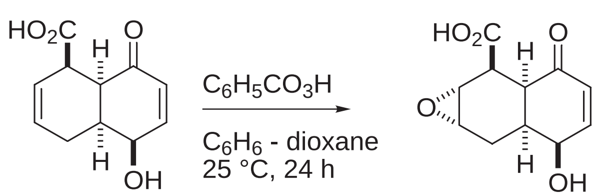


- Examples

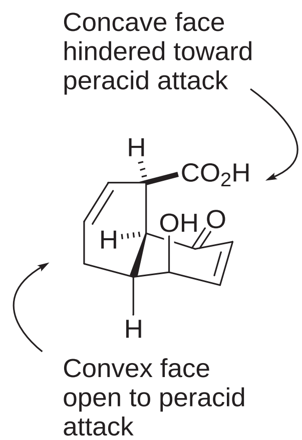


cis : *trans* 1 : 1





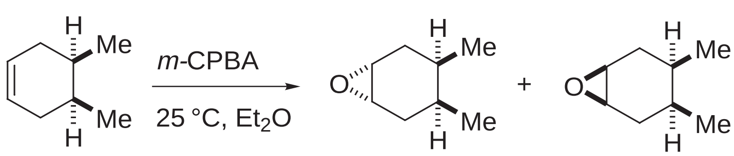
80%



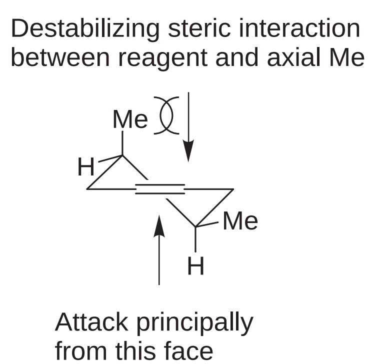
Hückel *Chem. Ber.* **1955**, *88*, 346.
Woodward *Tetrahedron* **1958**, *2*, 1.
Tamm, C. *Helv. Chim. Acta* **1975**, *58*, 1162.

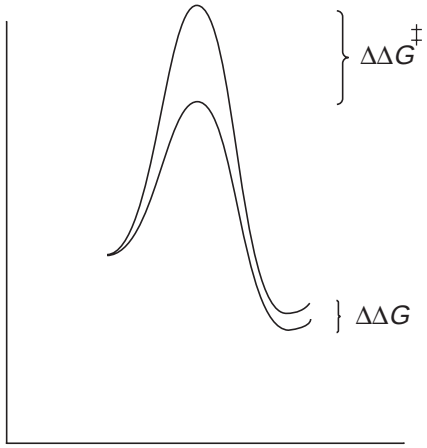
5. Diastereoselectivity

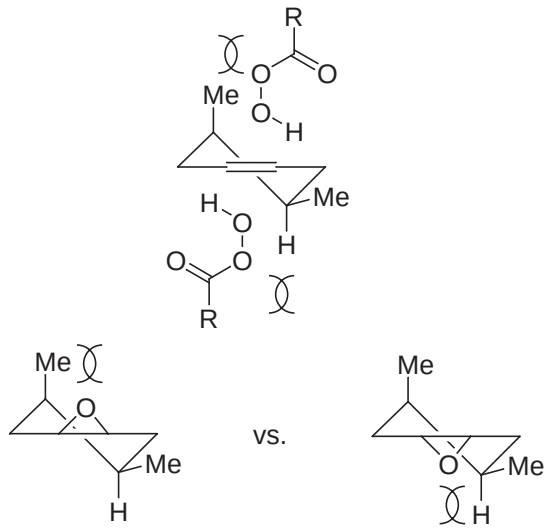
a. Endocyclic Olefins Rickborn *J. Org. Chem.* **1965**, *30*, 2212.



87 : 13

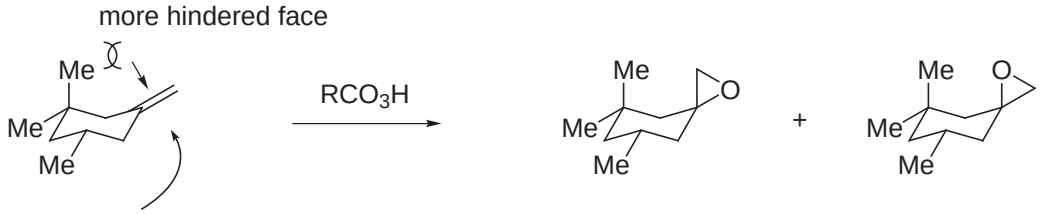






Small difference for products: but larger difference for reagent approach in transition state.

b. Exocyclic Olefins

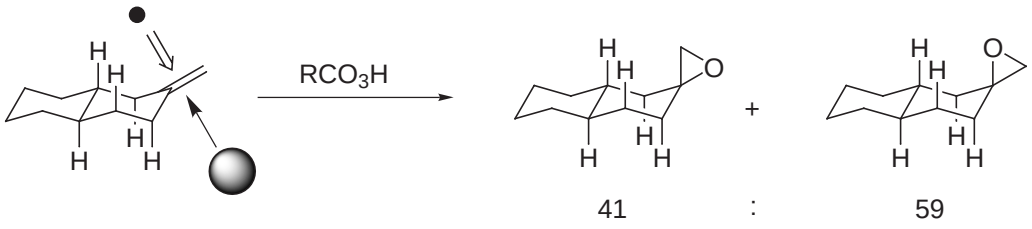


– Solvent dependent	CCl_4	75%	25%
	C_6H_6	80%	20%
	CH_2Cl_2 or $CHCl_3$	83%	17%

Henbest *J. Chem. Soc., Chem. Commun.* **1967**, 1085.

– The effective size of the reagent increases with increasing solvent polarity, i.e. the solvation shell of the reagent increases in size.

– Small reagent preference: axial attack and 1,3-diaxial interactions vary with size of the reagent

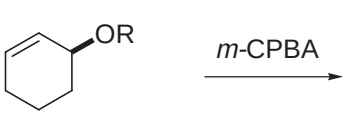


– Large reagent preference: equatorial attack and 1,2-interactions (torsional strain) are relatively invariant with the size of the reagent

Carlson *J. Org. Chem.* **1967**, *32*, 1363.

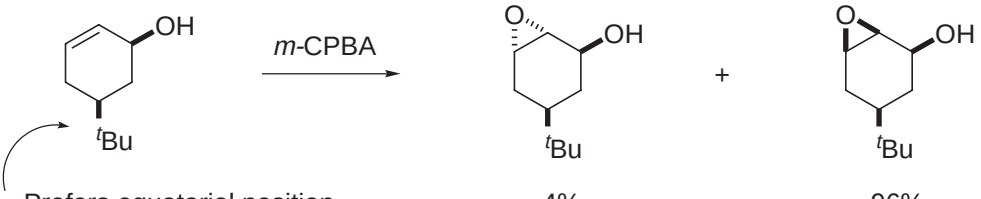
c. Allylic Alcohols (endocyclic)

Henbest *J. Chem. Soc.* **1957**, 1958; *Proc. Chem. Soc.* **1963**, 159.



R = $COCH_3$	20 °C C_6H_6	43%	57%	38% yield
R = H	5 °C C_6H_6	9%	91%	86% yield

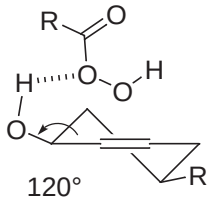
– Diastereoselectivity and rate (*ca.* 10x) of reaction accelerated by unprotected allylic alcohol.



Prefers equatorial position, locking conformation of substrate

4% 96%

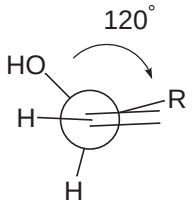
– Original proposal for the origin of selectivity:



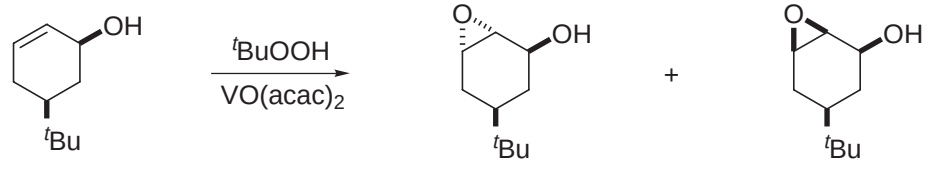
R = H, *t*Bu

H-bonding to proximal peroxide oxygen directs epoxidation to the same face as OH group and accelerates/facilitates the reaction.

– Equivalent to the ground state eclipsed conformation of acyclic allylic alcohols:



– Metal-catalyzed epoxidations of allylic alcohols exhibit a more powerful directing effect and rate acceleration (*ca.* 1000x). Metal bound substrate (as an alkoxide) delivers olefin to metal bound peroxide (tighter association than H-bonding).

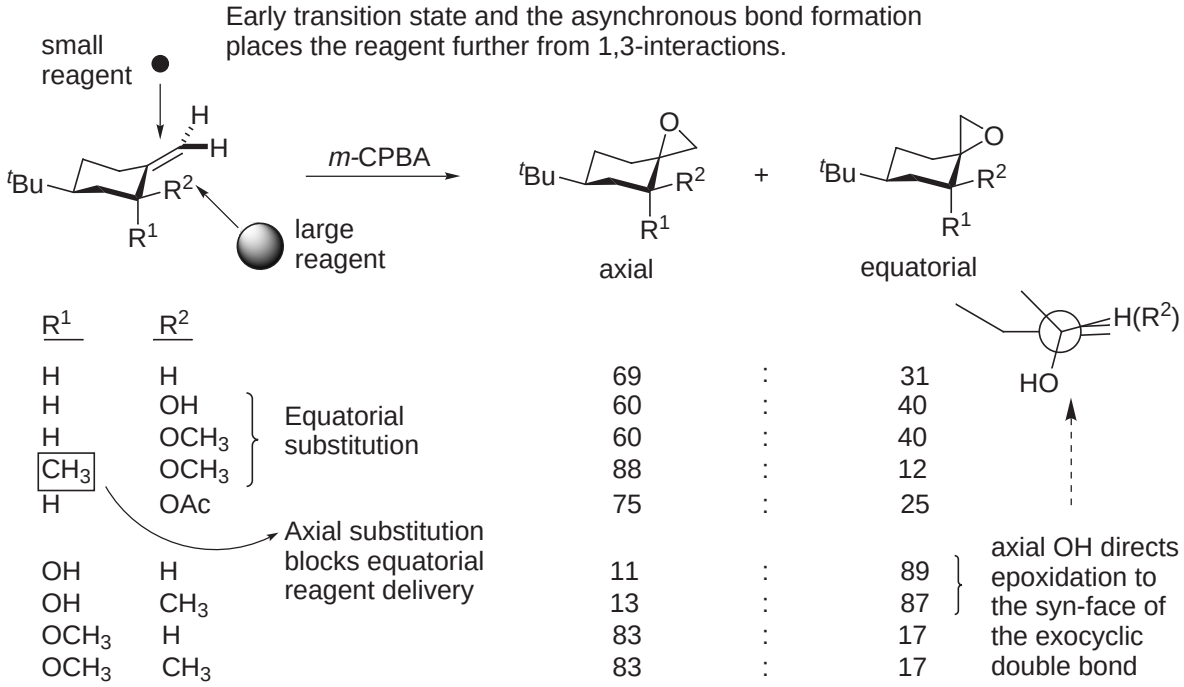


83% 0% 100%

Sharpless *Aldrichimica Acta* **1979**, *12*, 63.

– This may also be utilized to chemoselectively epoxidize an allylic alcohol vs. unactivated olefin.

d. Allylic Alcohols (exocyclic)



R^1	R^2				
H	H		69	:	31
H	OH	Equatorial substitution	60	:	40
H	OCH_3		60	:	40
CH_3	OCH_3		88	:	12
H	OAc		75	:	25
OH	H	Axial substitution blocks equatorial reagent delivery	11	:	89
OH	CH_3		13	:	87
OCH_3	H		83	:	17
OCH_3	CH_3		83	:	17

Vedejs and Dent *J. Am. Chem. Soc.* **1989**, *111*, 6861.

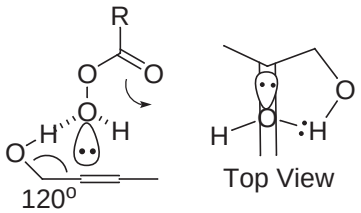
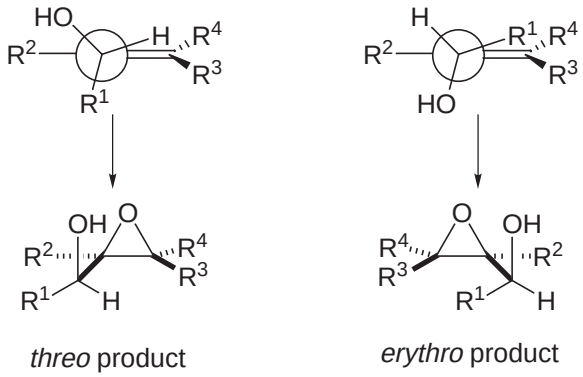
f. Refined Models for Directed Epoxidation of Acyclic Allylic Alcohols

– Peracid Mediated Epoxidation Sharpless *Tetrahedron Lett.* **1979**, 4733.

1. *Trans* antiperiplanar arrangement of O-O bond with alkene C=C.
2. H-bonding to distal oxygen of peroxide through the lone pair out of the plane of reaction.
3. Lone pair in plane of reaction provides π^*–lone pair (n-π^*) stabilization.
4. Secondary isotope effect suggests that the formation of the C-O bonds is asynchronous.

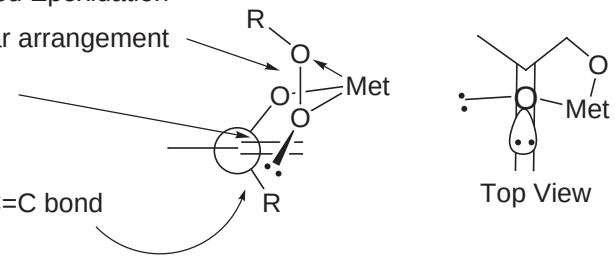


– Eclipsed Conformations in *m*-CPBA Epoxidation Sharpless *Aldrichimica Acta* **1979**, *12*, 63.



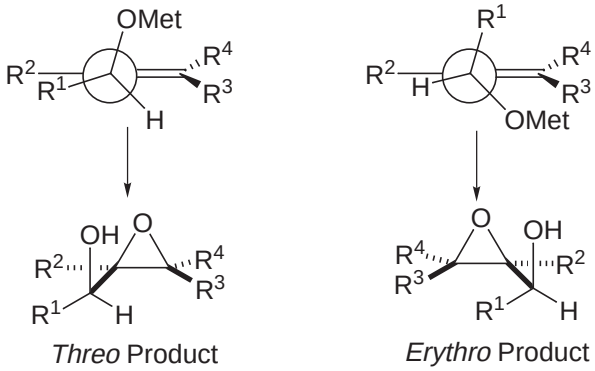
– Transition-metal Catalyzed Epoxidation

1. *Trans* antiperiplanar arrangement
2. 50° dihedral angle
3. In-plane lone pair
4. Lone pair bisects C=C bond



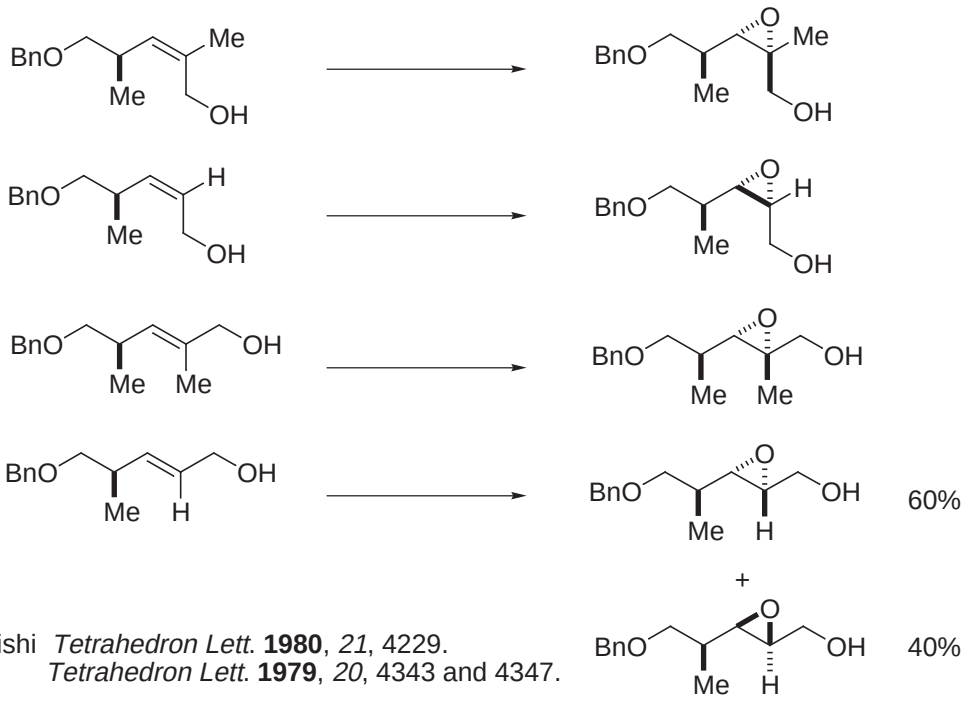
– Curtin-Hammett Principle:
- The reactive conformation is not necessarily related to the ground state conformation.
- The substrate is forced into a non-ground state conformation due to the geometrical constraints of the reaction.

– Bisected Conformations in Metal-Catalyzed Epoxidation



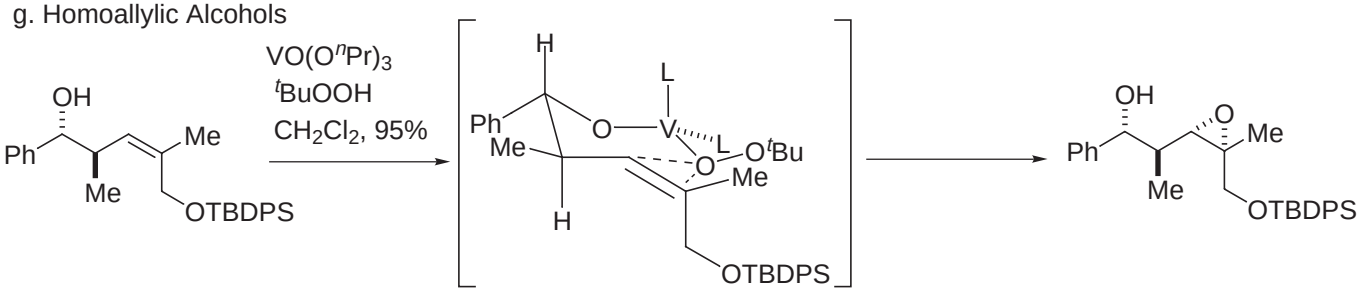
Take Home Problem

Epoxidation of 3 of the 4 olefins below is diastereoselective; the fourth is not. Why?



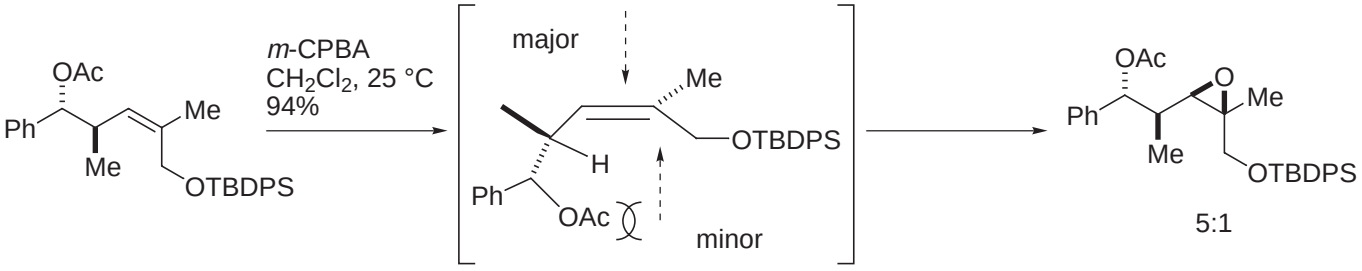
references: Kishi *Tetrahedron Lett.* **1980**, *21*, 4229.
Tetrahedron Lett. **1979**, *20*, 4343 and 4347.

g. Homoallylic Alcohols



- Alternative chair has two axial substituents.
- Intramolecular oxygen delivery occurs through most stable chair-like transition state.

VS.

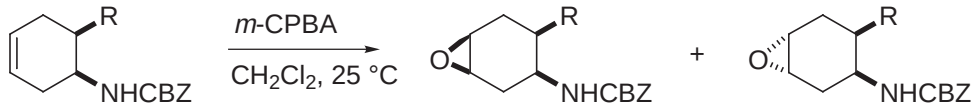


- H-Eclipsed conformation
- Epoxidation from least hindered face
- Not a directed epoxidation!
- Diastereoselectivity still good and through H-eclipsed conformation.

Schreiber *Tetrahedron Lett.* **1990**, *31*, 31.
Hanessian *J. Am. Chem. Soc.* **1990**, *112*, 5276.

h. Other Directed Epoxidations

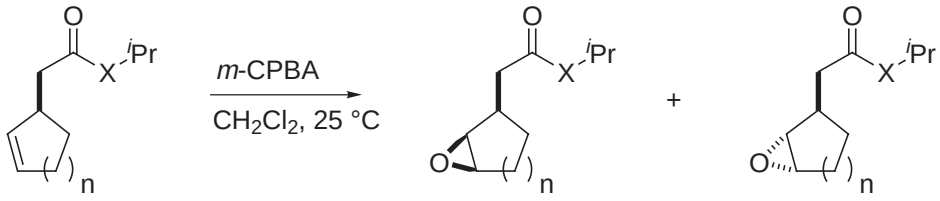
– Studies suggest axial -NHCBZ delivers syn epoxide while equatorial does not.



R = NHCBZ	86%	100	0
= CH_2OH	83%	100	0
= CH_2OAc	72%	100	0
= CO_2Me	59%	100	0
= $CH_2OTBDMS$	54%	0	100

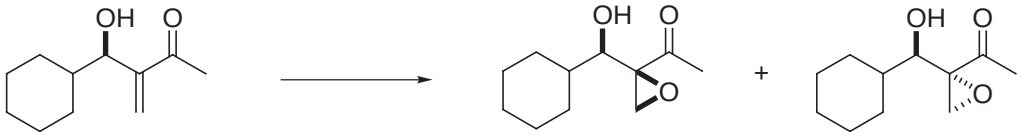
Presence of H-bonding, directing substituent enhances rate and yield of reaction.

Witiak *J. Med. Chem.* **1989**, *32*, 214.
Rotella *Tetrahedron Lett.* **1984**, *30*, 1913.



n = 1, X = NH	80%	20	1
X = O		3	1
n = 2, X = NH		20	1
X = O		3	1

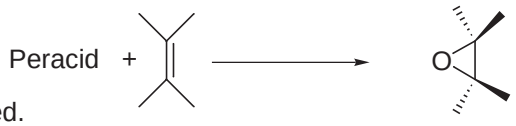
Mohamadi *Tetrahedron Lett.* **1989**, *30*, 1309.



H_2O_2 / NaOH / MeOH / 0 °C	40	:	60
Ti(^{i}PrO)$_4$ / ^{t}BuOOH / CH_2Cl_2 / –15 °C	>99	:	1

Ollis *Tetrahedron Lett.* **1991**, *32*, 2687.

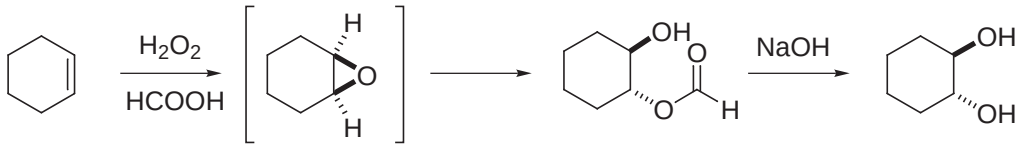
6. Scope and Limitations



a. Olefin geometry is maintained.

b. Reaction is **diastereospecific**: the stereochemistry of the reactant and product bear a definite relationship to one another.

c. Reaction can be buffered to prevent epoxide opening. The pK_a of parent acid is much lower than that of the peracid, and the peracid is not nearly as acidic. Reaction requires the protonated peracid so the buffer must not deprotonate the peracid but should deprotonate the product carboxylic acid.



Na_2CO_3 / $NaHCO_3$
CH_3COOH / NaOAc
CF_3CO_3H / Na_2HPO_4 - NaH_2PO_4

} These reagents can be used as a buffer when the peracids are used as epoxidation reagents.

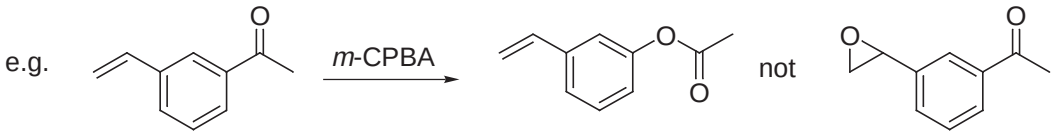
e.g. HCOOH pK_a 3.6 CH_3COOH pK_a 4.8
HCO_3H pK_a 7.1 CH_3CO_3H pK_a 5.2

– So, choose bases (Na_2CO_3, $NaHCO_3$, Na_2HPO_4) to deprotonate only the RCOOH formed.

d. Also, at higher temperatures, a free radical scavenger may be used to avoid peracid decomposition.

e. Common Side Reactions

1. Baeyer-Villiger reactions of ketones (and aldehydes)



– When peracids are used to oxidize olefins to epoxides in the presence of carbonyl functionality (ketones or aldehydes), protection of the carbonyl group may be necessary.

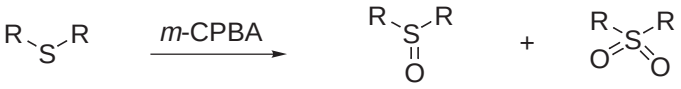
– One may choose to select a reagent which attacks olefins preferentially.

2. Oxidation of amines

– Nitrogen must be protected (e.g., as amide) or another reagent selected.

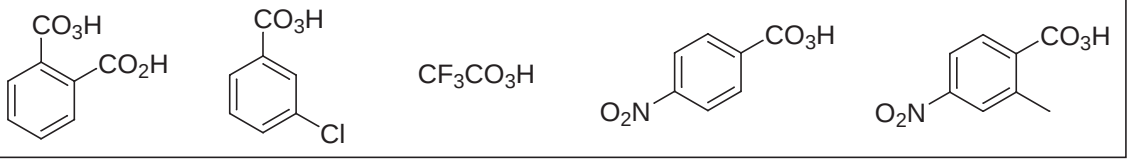
3. Imine oxidation

4. Sulfur oxidation



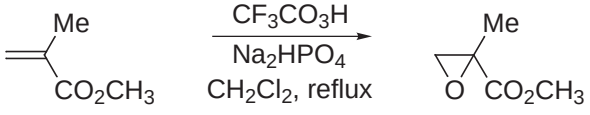
Typical Peracids

m-CPBA

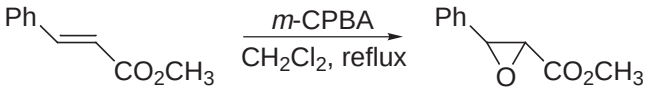


7. Epoxidation of Electron-Deficient Olefins

a. α,β-unsaturated esters: can choose a strong peracid or vigorous reaction conditions

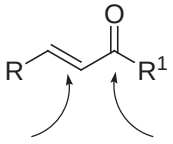


84% Emmons *J. Am. Chem. Soc.* **1955**, *77*, 89.



47% MacPeek *J. Am. Chem. Soc.* **1959**, *81*, 680.

b. α,β-unsaturated ketones: Baeyer-Villiger competes with epoxidation

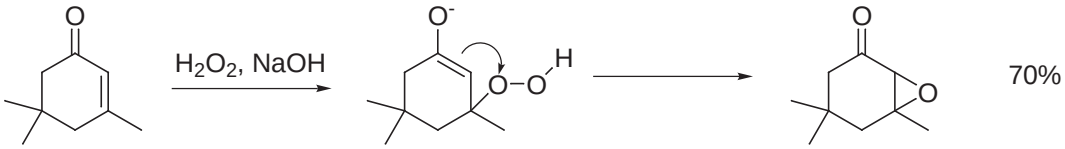


Epoxidation Baeyer-Villiger Reaction

Solution: different conditions (reagents) are needed

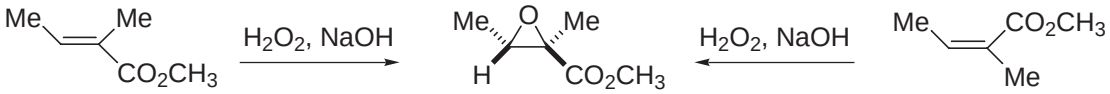
B. Additional Methods for Epoxidation of Olefins

1. H_2O_2, NaOH

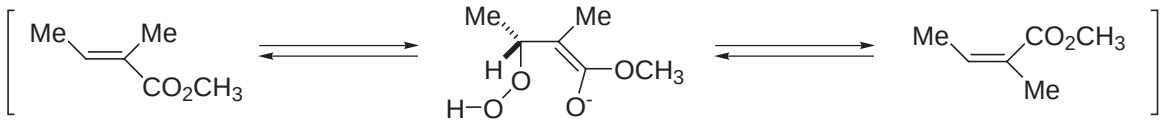


70%

– The following reaction is **diastereoselective** (but not diastereospecific): a single stereoisomer of the product is formed which bears no relationship to the reactant.



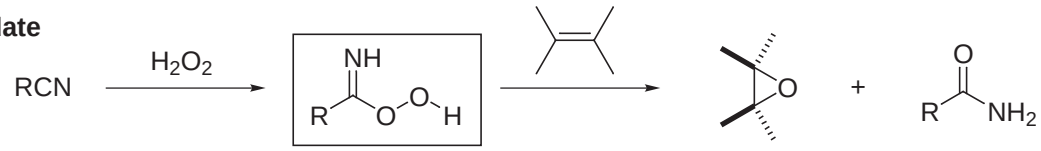
The reaction occurs via a reversible process:



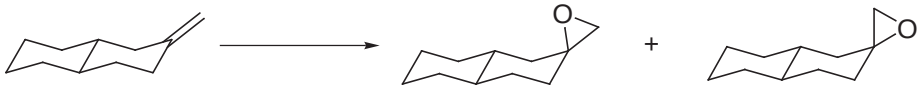
Similarly,

^{t}BuOOH/Triton B	Payne *J. Org. Chem.* **1961**, *26*, 651.
Ph_3COOH/R_4NOH	Corey *J. Am. Chem. Soc.* **1988**, *110*, 649.
^{t}BuOOH/^{n}BuLi	Clegg *Tetrahedron* **1988**, *29*, 4889.

2. Peroxyimidate



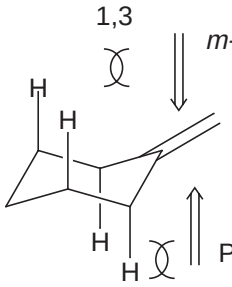
– This reagent permits the use of neutral reaction conditions. Unlike *m*-CPBA, the reagent behaves as a large reagent and thus approaches from the equatorial face of an exocyclic double bond.



small reagent ⟸	*m*-CPBA	59	41
large reagent ⟸	PhCN / H_2O_2	14	86

Carlson *J. Org. Chem.* **1967**, *32*, 1363.
(*m*-CPBA & $PhCN/H_2O_2$)

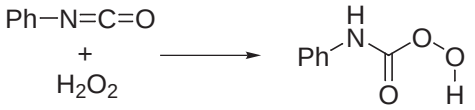
Vedejs *J. Am. Chem. Soc.* **1989**, *111*, 6861.
(*m*-CPBA)



small reagent, but the interaction will increase with the size of the reagent

larger reagent, but the interaction will not vary with size, predominately equatorial attack

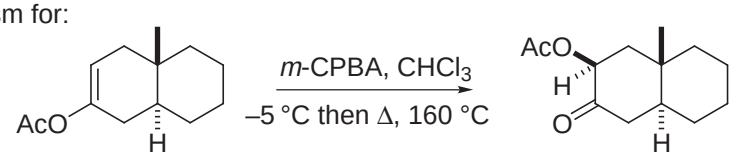
–Analogous reagent:

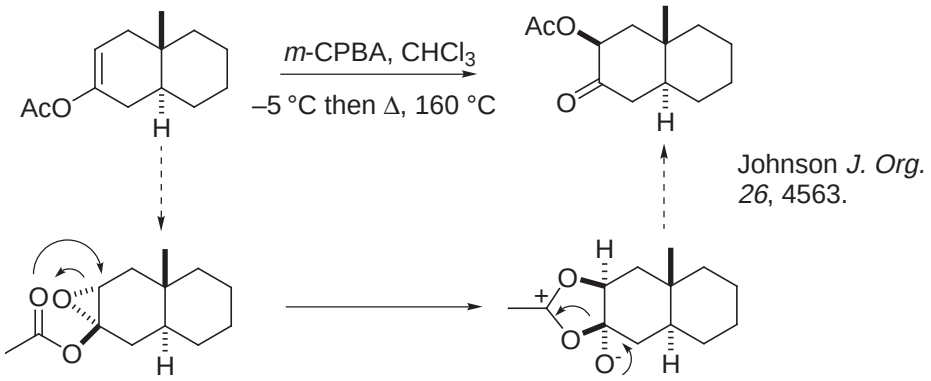


Christl *Angew. Chem., Int. Ed. Eng.* **1980**, *19*, 458.

Mechanism Problem

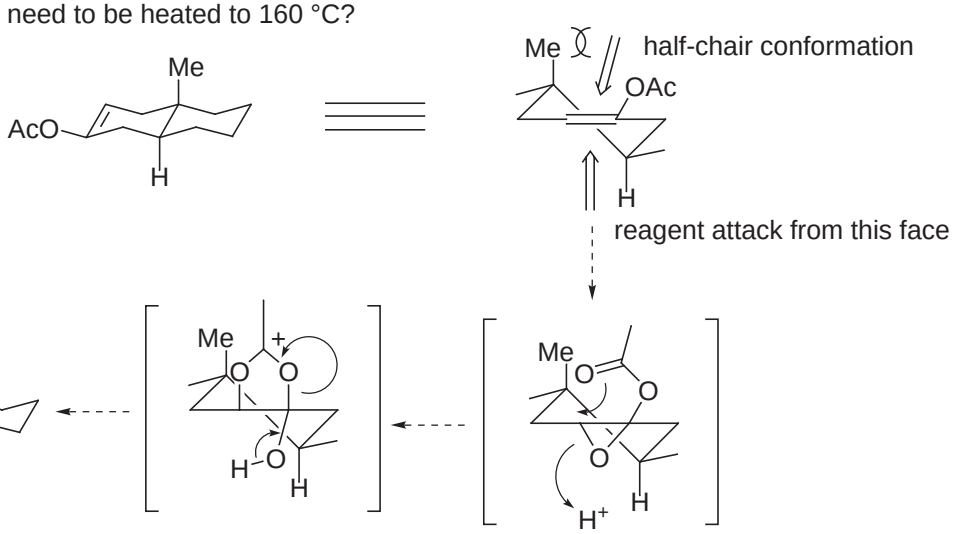
Provide mechanism for:



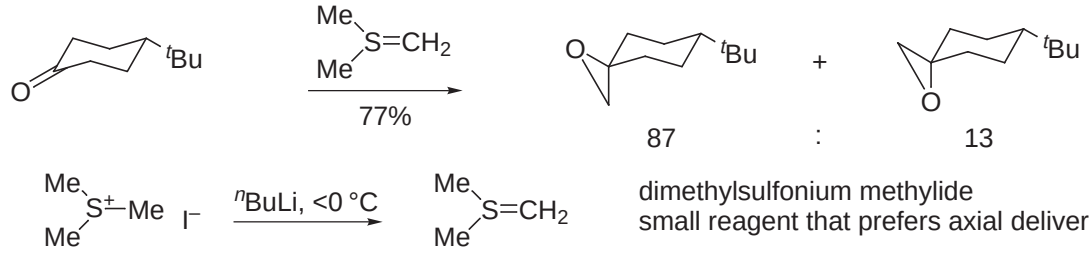


Johnson *J. Org. Chem.* **1961**, *26*, 4563.

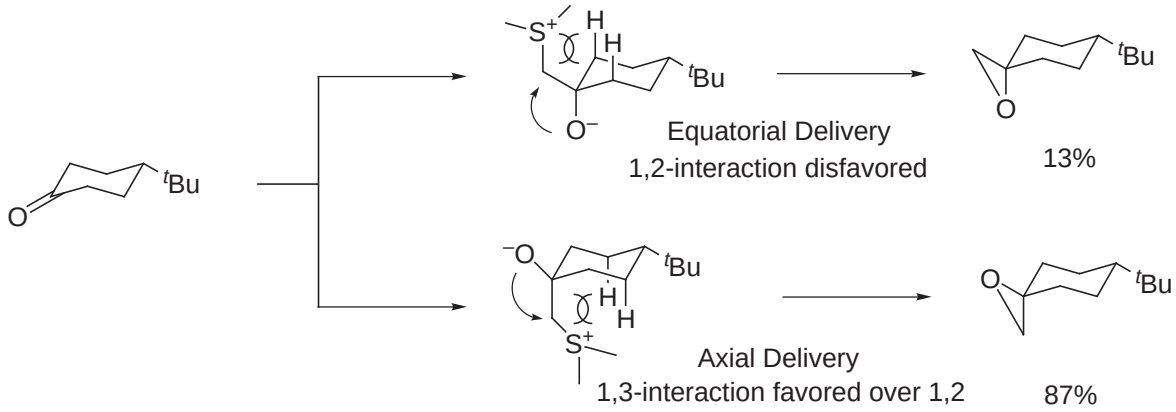
Why does this reaction need to be heated to 160 °C?

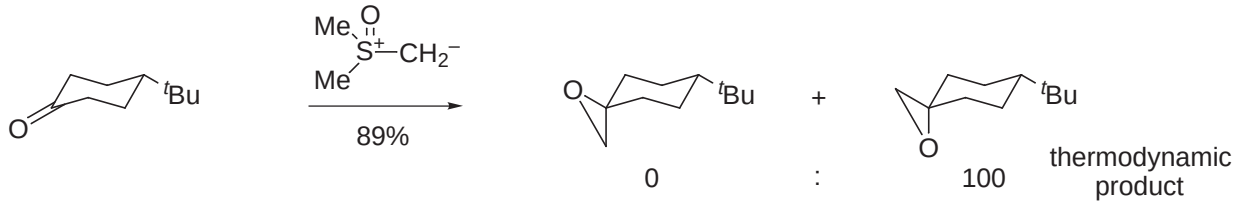


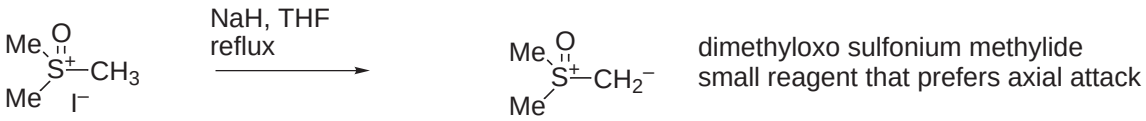
3. Sulfur Ylides



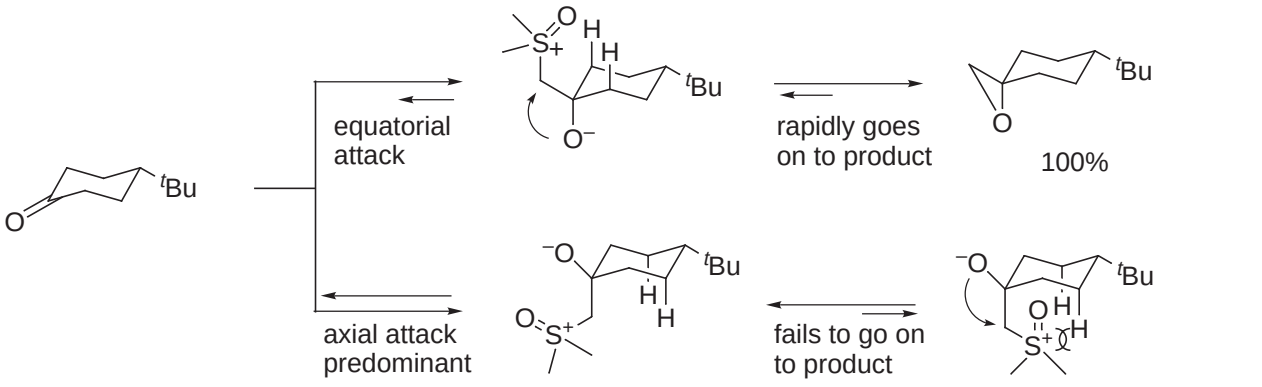
– This is kinetic control: reaction gives the thermodynamically less stable epoxide product.







Corey, Chaykovsky *J. Am. Chem. Soc.* **1965**, *87*, 1353.

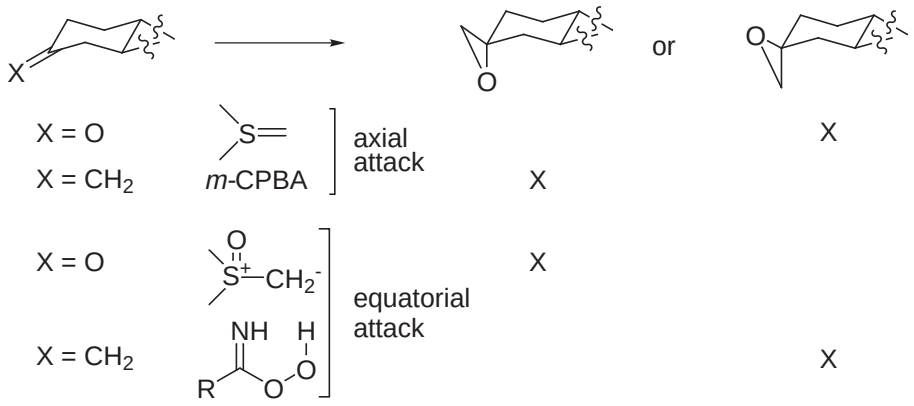


backside attack not possible due
to destabilizing 1,3-interactions

For this reaction: Initial reaction is reversible and is not capable of generating the axial delivery product because of the destabilizing 1,3-interactions in the transition state required for epoxide closure.

Summary of Exocyclic Epoxide Formation

Note: defined conformation of 6-membered ring required for comparisons



Sulfur ylides deliver "CH_2"
Peroxides deliver "O"

Learn reagents by:
1) Conditions required
2) Advantages and disadvantages
3) Competitive reactions

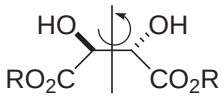
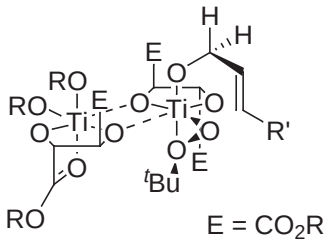
1,2,2-trisubstituted	$R^3 = H$	>95% ee	70-80%

4. Sharpless asymmetric epoxidation is one of the best known and practical asymmetric reactions utilized in organic synthesis. Discovered in 1980, this catalytic process utilizes an optically active ligand to direct a transition metal catalyzed reaction. Epoxidation from a single face of a prostereogenic allylic alcohol:



C^2 symmetry



(Useful in ligand design- predictable and repetitive structural units which reduce number of diastereomeric transition states)

a. Match of Ti / Tartrate such that a single complex dominates the chemistry.

The concentration of each complex in the mixture of complexes is dictated by thermodynamic considerations. However, it could not be predicted that a single species would dominate the Ti-tartrate equilibrium mixture and that this species would be so kinetically active. The tartrate-Ti complex is perfectly matched and slight deviations in the ligand structure or change in the metal alkoxide reduces the effectiveness of the reaction.

b. Ligand acceleration of reaction.

This is not essential but extremely beneficial. It ensures that the enantioselective version of the reaction (the one in which the auxiliary ligand is present) will be the most viable kinetic pathway.

c. Steric and stereoelectronic features of reaction control enantioselectivity.

Stereoelectronic:

1. Alkyl peroxide is activated by bidentate coordination to the Ti(IV) center.
2. The olefin is constrained to attack the coordinated peroxide along the O-O bond axis. (stereoelectronic effect)
3. The epoxide C-O bonds are formed simultaneously.

Steric factors:

1. Bulky hydroperoxide is forced to adopt a single orientation when bound in a bidentate fashion.
2. The allylic alkoxide is thereby restricted to reaction at a single coordination site on the metal center. Steric interactions of the bound substrate with the catalyst framework provide for the kinetic resolution patterns.
3. Efficient catalytic turnover provided by the labile coordinated ester, permitting rapid alkoxide-alcohol exchange.

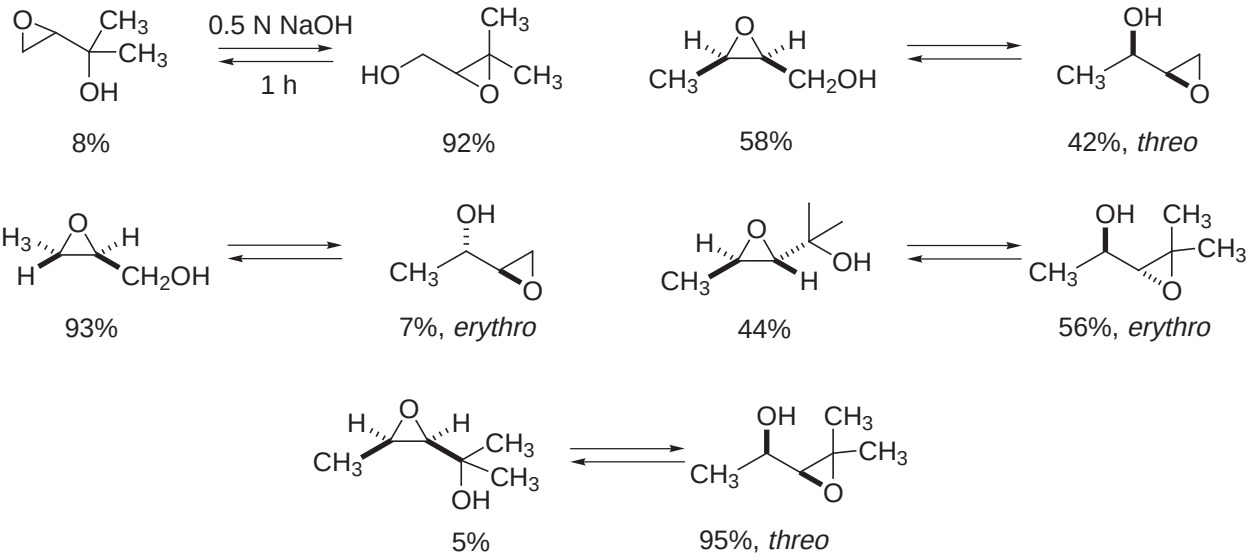
For b, d, f, and h: 1. Pummerer reaction, 2. K_2CO_3/MeOH, 3. Deprotection.

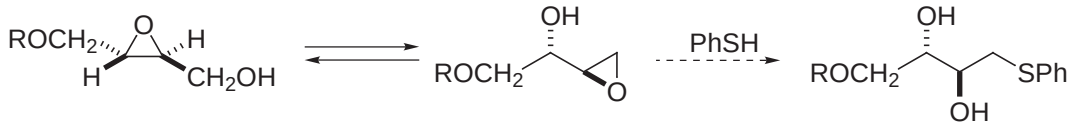
-Payne Rearrangement

Payne *J. Org. Chem.* **1962**, *27*, 3819.

Base-catalyzed (aq. NaOH) migration of α,β-epoxy alcohols:



1. In general, the more substituted epoxide is favored as the reaction product.
2. However, steric factors and relative alcohol acidities (1° > 2° > 3°) are additional factors which determine the ultimate composition of the equilibrium mixture.
3. The more reactive epoxide can be trapped by strong nucleophiles (e.g., PhSH).



Emil Fischer attended the lectures of A. Kekule, worked with A. Baeyer as a student and received the 1902 Nobel Prize in Chemistry for his work on carbohydrate and purine syntheses. Discoverer of the Fischer indole synthesis using arylhydrazones, he utilized phenylhydrazine to derivatize carbohydrates as crystalline solids for characterization that enabled him to elucidate their chemistry and structure. From the work of Le Bel and van't Hoff he knew glucose must have 16 stereoisomers and in the now classic studies synthesized most of them and established the correct configuration of glucose. He proposed structures for uric acid, caffeine, theobromide, xanthine, and guanine and later synthesized theophylline and caffeine (1895), uric acid (1897), and coined the term purine. By 1900 he prepared more than 130 derivatives including hypoxanthine, xanthine, theobromide, adenine, and guanine. In 1914, he made glucose derivatives and from them the nucleosides. He is responsible for the "lock and key" analogy for describing enzyme-substrate interactions, prepared the D- and L-amino acids with fractional crystallization resolution and made a peptide of 18 amino acids. He is also among the first to implement safety precautions (ventilation) and designed the first exhaust system put into general use.

W. Haworth received the 1937 Nobel Prize in Chemistry for his investigations on the structure determination of carbohydrates (cyclic-monosaccharides, disaccharides, and polysaccharides) including their derivitization as methyl ethers and vitamin C. The latter was accepted with wide acclaim and Haworth was also one of the first to prepare vitamin C, the first vitamin to be prepared by synthesis. This made it available to the world population for the treatment of scurvy, eliminating the need for treatment with fresh limes or lemons.

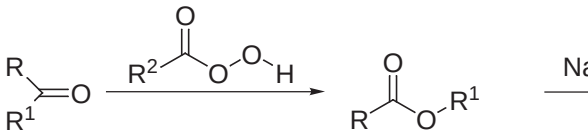
Org. React. **1957**, *9*, 73; **1993**, *43*, 251.

A. Baeyer received the 1905 Nobel Prize in Chemistry for his work on dyes (indigo). He also discovered barbituric acid and named it after his girlfriend Barbara.

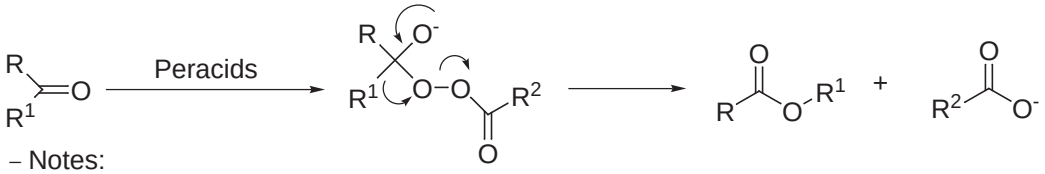
1. Baeyer-Villiger Reaction



Baeyer, Villiger
Ber. **1899**, *32*, 3625.
Ber. **1900**, *33*, 858.

Note: Sometimes the Baeyer-Villiger reaction is used not only for preparing carboxylic acids or esters, but also for ROH.

– Mechanism: (Peracid nucleophilic addition reaction)

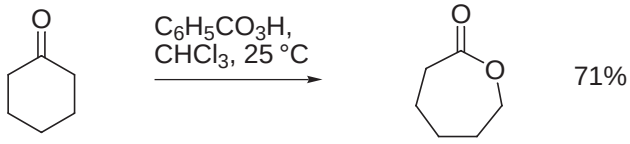


– Notes:

1. Alkyl group that migrates does so with retention of configuration.
2. The more electron-rich (most-substituted) alkyl group migrates in preference (in general).
   ^{t}alkyl > ^{s}alkyl > benzyl > phenyl > ^{n}alkyl > methyl
   Thus, methyl ketones invariably provide acetates.

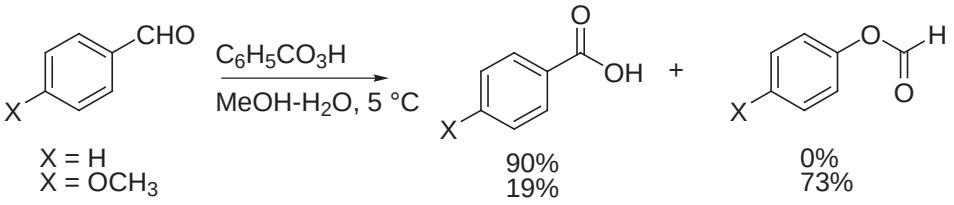
– Examples:

Friess *J. Am. Chem. Soc.* **1949**, *71*, 2571.



71%

Ogala *J. Org. Chem.* **1969**, *34*, 3985.

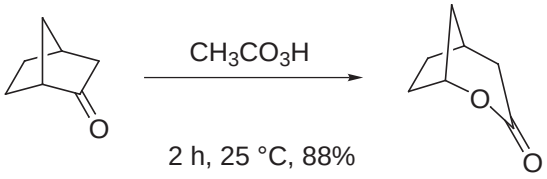


X = H
X = OCH_3

90%
19%

0%
73%

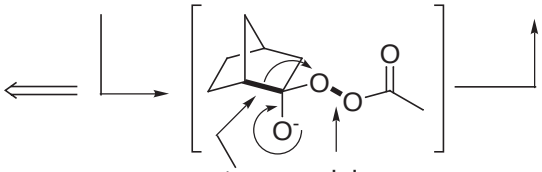
Meinwald *J. Am. Chem. Soc.* **1960**, *82*, 5235.



2 h, 25 °C, 88%

– Nucleophilic attack from least hindered exo face.

Migrating C-C bond and O-O bond must be trans-antiperiplanar

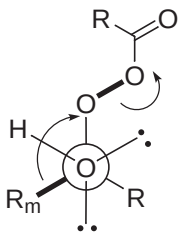


trans-periplanar

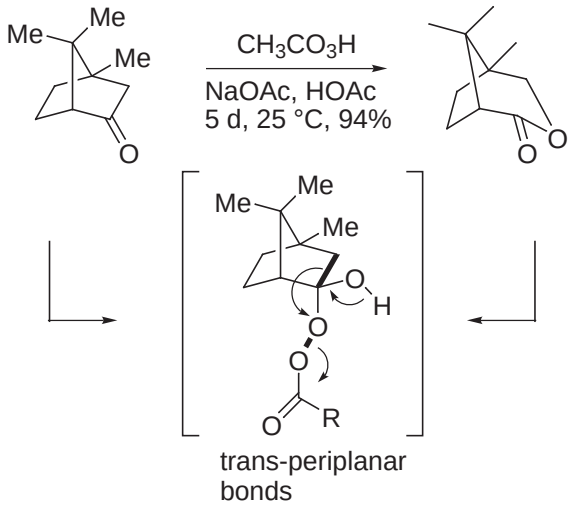
– Most substituted (electron-rich) carbon migrates.

– Antiperiplanar arrangement of C-R_m bond and the breaking O-O bond (stereoelectronic requirement).

– Hydroxyl lone pair or O-H bond antiperiplanar to the migrating C-R_m bond.



Sauers *J. Am. Chem. Soc.* **1961**, *83*, 2759.



– In contrast to simple expectations, the less electron-rich bond migrates due to stereoelectronic considerations.

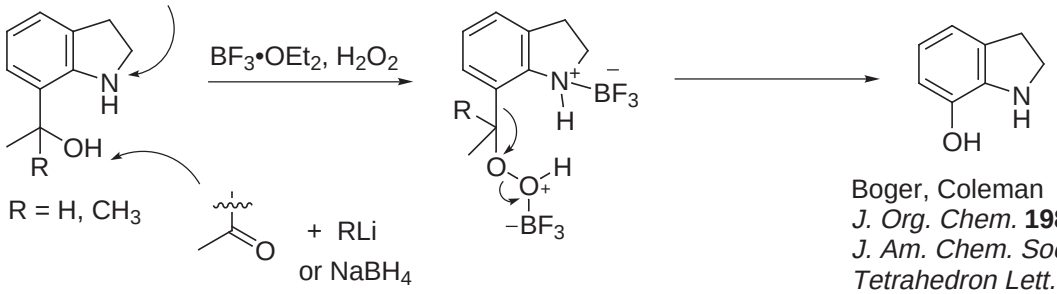
– Nucleophilic attack from endo face, exo face blocked by Me's.

– Reaction much slower than norbornone.

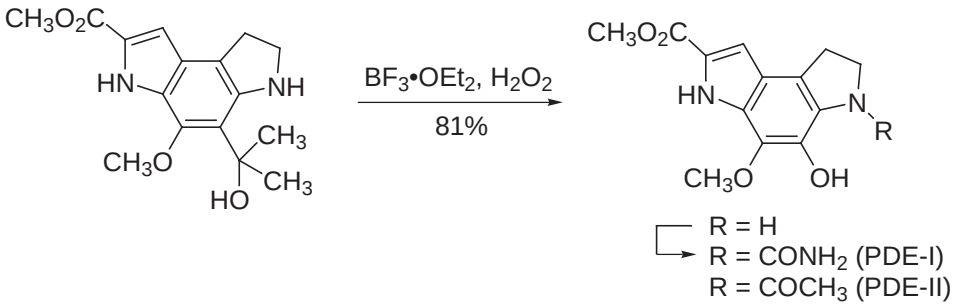
2. Benzylic Hydroperoxide Rearrangement

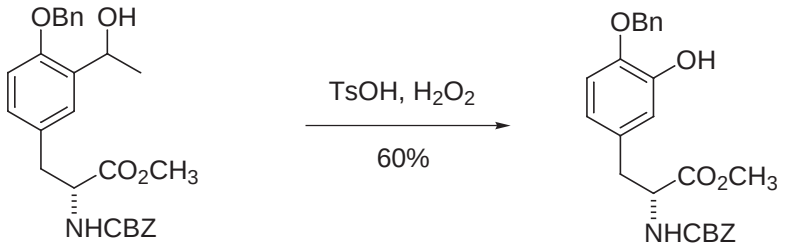
– Alternative to Baeyer-Villiger Reaction

Would be oxidized by peracid



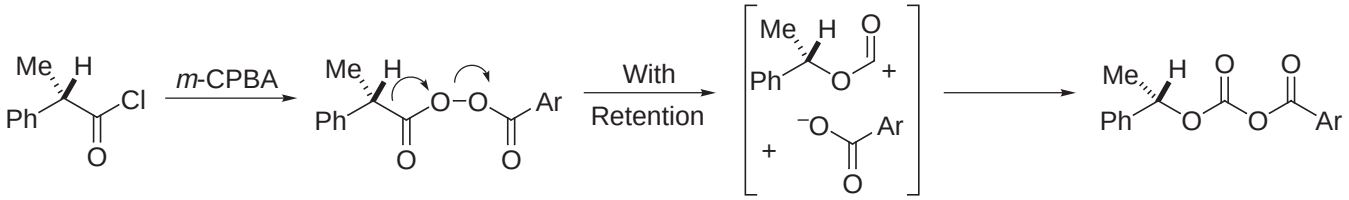
Boger, Coleman
J. Org. Chem. **1986**, *51*, 5436.
J. Am. Chem. Soc. **1987**, *109*, 2717.
Tetrahedron Lett. **1987**, *28*, 1027.



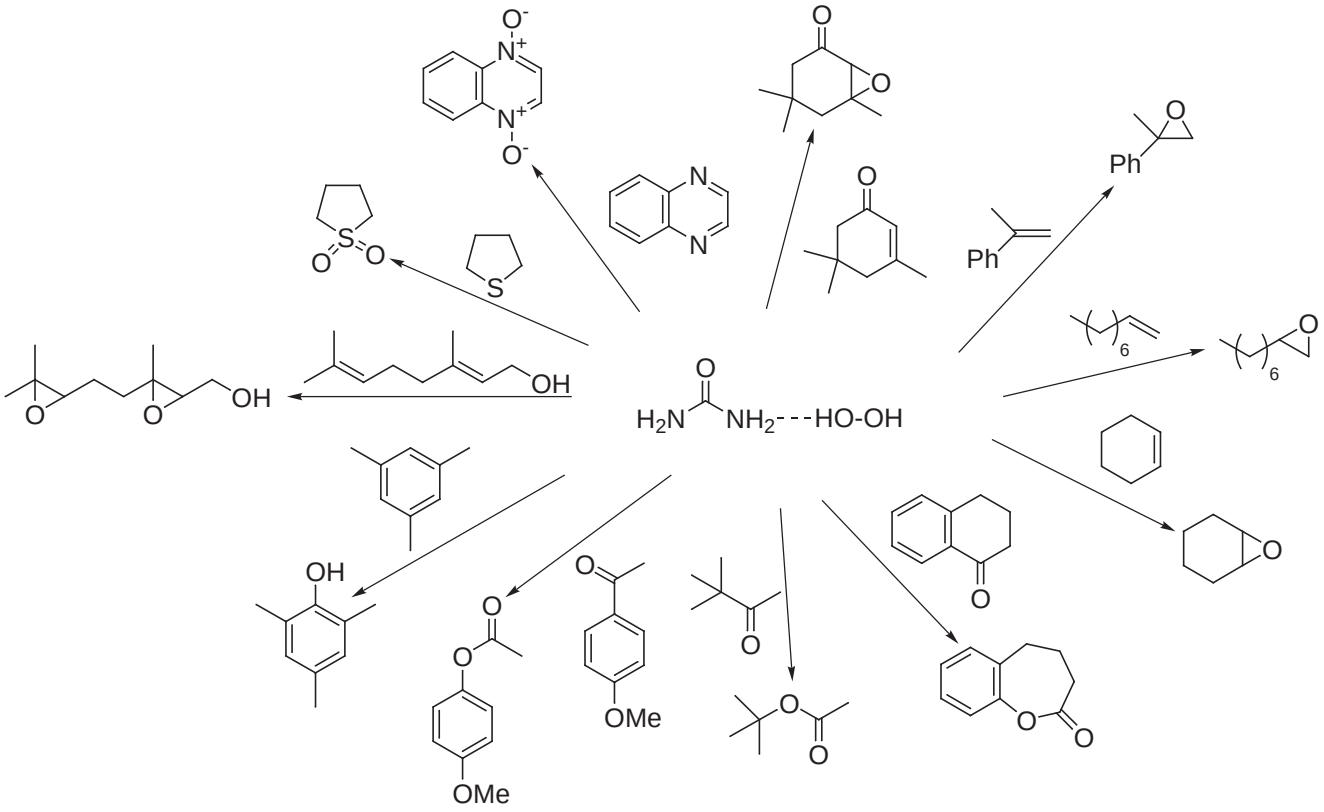


Boger, Yohannes
J. Org. Chem. **1987**, *52*, 5283.

3. Carboxy Inversion Reaction



4. Urea-H_2O_2: a safe alternative to H_2O_2 Heaney *Synlett* **1990**, 533.

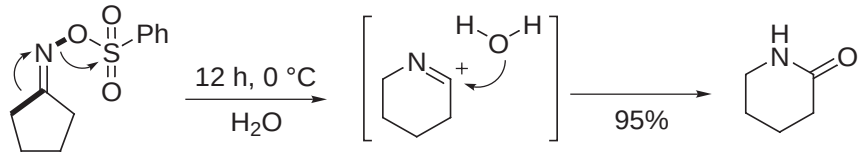


F. Beckmann Rearrangement and Related Reactions

– An analogous rearrangement reaction can be utilized to prepare lactams and amides.

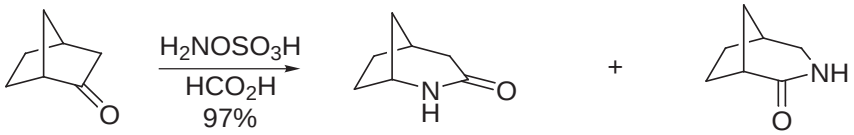
1. Beckmann Rearrangement

Heldt *Org. React.* **1960**, *11*, 1
Gawley *Org. React.* **1988**, *35*, 1.
Comprehensive Org. Syn., Vol. 7, pp 689-702.

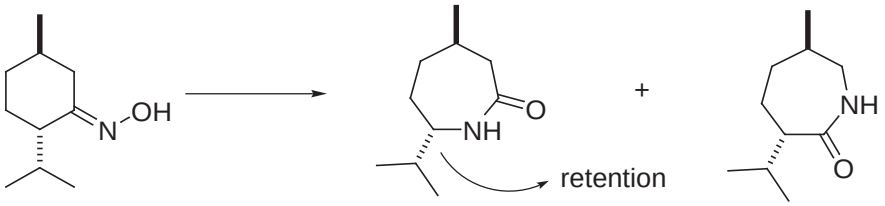


– Prepared from the oxime. Beckmann *Ber.* **1886**, *89*, 988.
– A wide range of leaving groups and catalysts have been utilized.

1. Group anti to oxime leaving group migrates.
2. The alkyl group migrates with retention of configuration.



Note: Isomerization of oxime or its activated derivative may occur under the reaction conditions and fragmentation to a nitrile may compete when the migrating center is 3°.

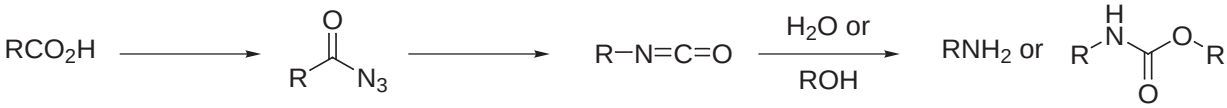


$POCl_3$, pyridine	98%	2%
$SOCl_2$, pyridine	90%	10%
20% aq. H_2SO_4	43%	57%
HCl / Et_2O	5%	95%

2. Curtius Rearrangement

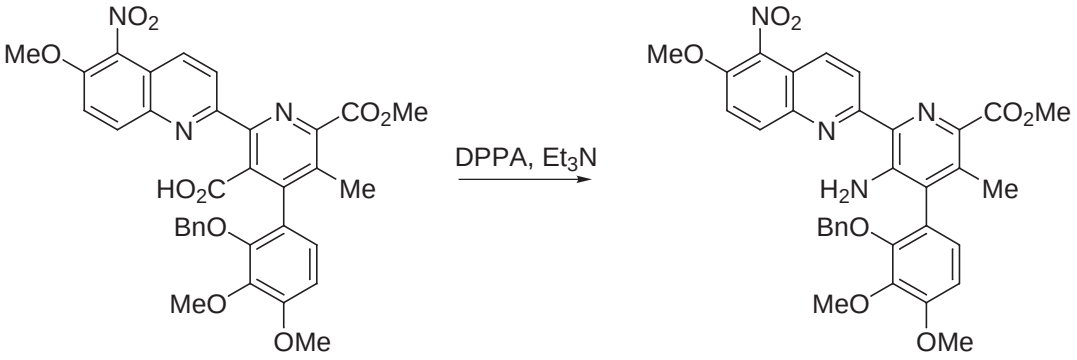
Smith *Org. React.* **1946**, *3*, 337.
Comprehensive Org. Syn., Vol. 6, pp 806-816.

Curtius *Ber.* **1890**, *23*, 3023. (initially not recognized)

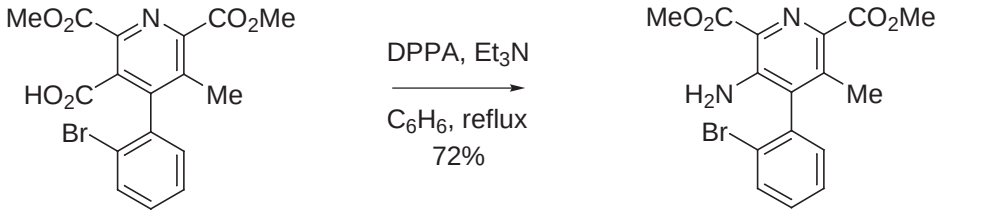


– $(PhO)_2P(O)N_3$ (DPPA) is a useful reagent for the direct conversion of carboxylic acids to acyl azides under *in situ* conditions for the rearrangement. Shiori, Yamada *Tetrahedron* **1974**, *30*, 2151.
– R group migrates with retention of configuration.

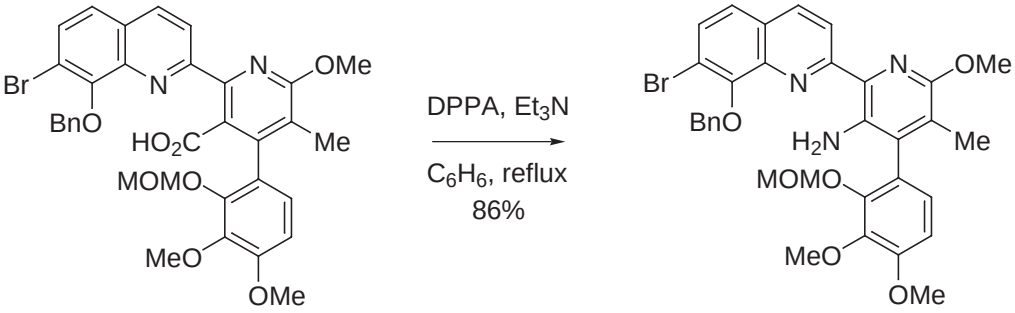
-Examples



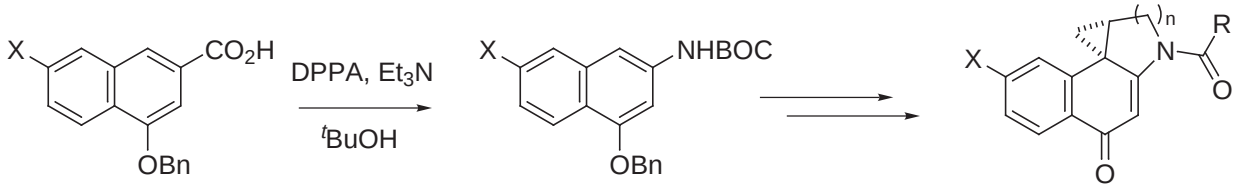
Boger, Panek
(streptonigrin)
J. Am. Chem. Soc.
1985, *107*, 5745.



Boger
(lavendamycin)
J. Org. Chem.
1985, *50*, 5782.



Boger
(streptonigrone)
J. Org. Chem. Soc.
1993, *115*, 10733.



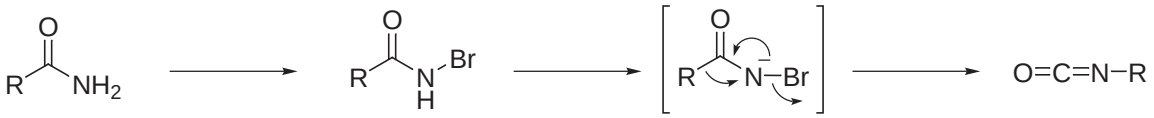
X = H, Br, CN, OMe

n = 1-3

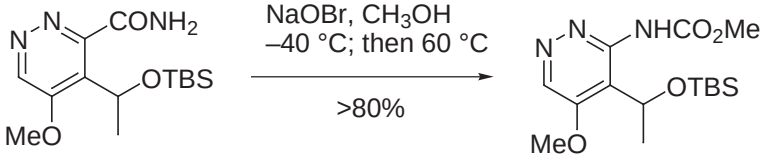
Boger *J. Org. Chem.* **1995**, *60*, 1271;
1996, *61*, 1710 and 4894;
1997, *62*, 5849.
J. Am. Chem. Soc. **1994**, *116*, 11335.
Synlett **1997**, 515.

3. Hofmann Rearrangement

Lane *Org. React.* **1946**, *3*, 267.
Comprehensive Org. Syn., Vol. 6, pp 806-816.



Hofmann *Ber.* **1881**, *14*, 2725.



Boger, Coleman
(PDE-I, PDE-II, CC-1065)
J. Org. Chem. **1986**, *51*, 3250.
J. Am. Chem. Soc. **1987**, *109*, 2717.

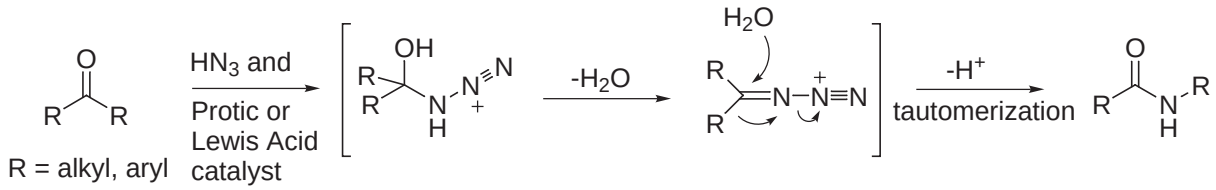
– Reagents employed include basic hypohalides, $Pb(OAc)_4$, $PhI(OCOCF_3)_2$, PhIO.
– R group migrates with retention of configuration.

4. Schmidt Reaction

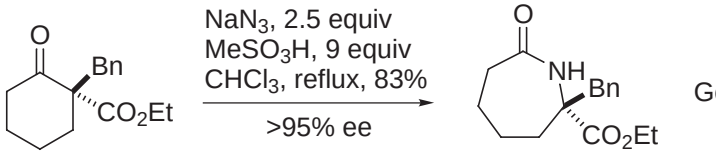
Schmidt *Angew. Chem.* **1928**, *36*, 511.
Wolff *Org. React.* **1946**, *3*, 307.
Comprehensive Org. Syn., Vol. 6, pp 817-821.

The Schmidt Reaction is a general name for what are three individual reactions:

A. Conversion of Ketones to Amides

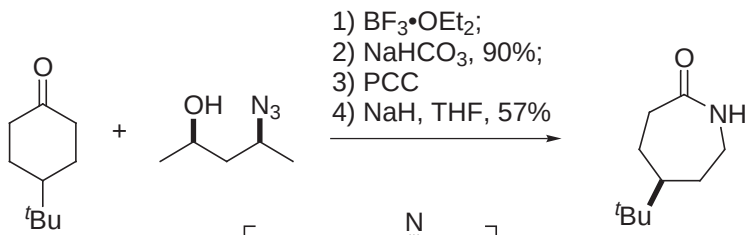


- Most studied of Schmidt variants, similar to Beckmann Rearrangement.
- Asymmetric variant (Aube) utilizes chiral alkyl azide donors which provide products in high diastereoselectivity.
- Bicyclic ketones slightly favor migration of less substituted group, opposite of Beckmann.
- Reactivity: dialkyl ketone > alkyl,aryl ketone > diaryl ketone > carboxylic acid or alcohol.

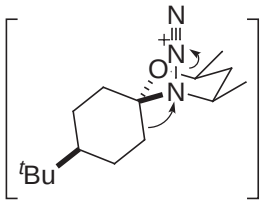


Georg *Bioorg. Med. Chem. Lett.* **1991**, *1*, 125.

retention of configuration

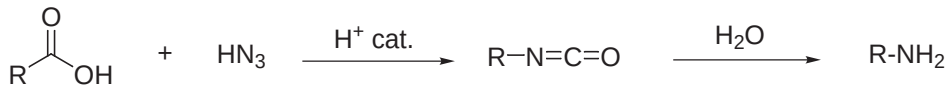


Aube *J. Am. Chem. Soc.* **1995**, *117*, 8047.



one diastereomer

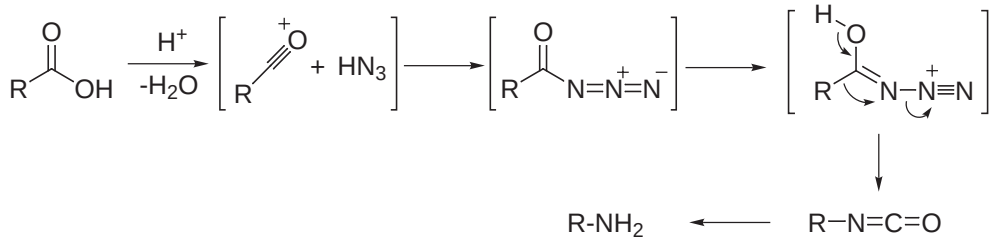
B. Conversion of Carboxylic Acids to Amines

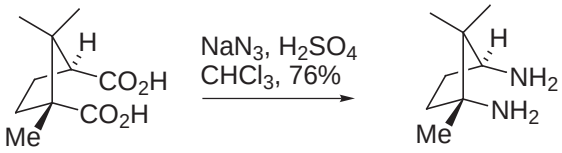


- Acid catalyst usually H_2SO_4, PPA, TFA-TFAA, or sometimes Lewis acid.
- Good results when R = alkyl, hindered alkyl or aryl.
- Advantage in process length over Hofmann and Curtius Rearrangements, but more drastic conditions.
- Mechanism controversy.

Hayes *J. Org. Chem.* **1979**, *44*, 3682.

Koldobskii *Russ. Chem. Rev.* **1978**, *47*, 1084.

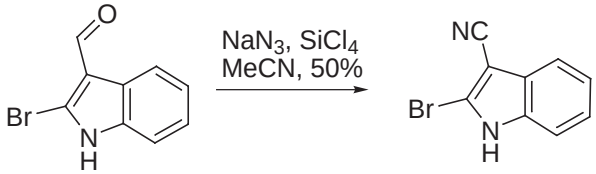




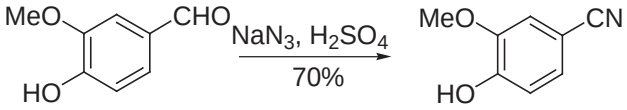
Sato *Tetrahedron: Asymmetry* **1992**, *3*, 5.

C. Conversion of Aldehydes to Nitriles

- Acid catalyst usually H_2SO_4, can be Lewis acid.
- Schmidt reaction is the usual byproduct under these conditions to provide formamide.
- More common method is to convert aldehyde to oxime with hydroxylamine, followed by dehydration.
- Aromatic aldehydes are good substrates.



Elmorsy *Tetrahedron Lett.* **1995**, *36*, 2639.

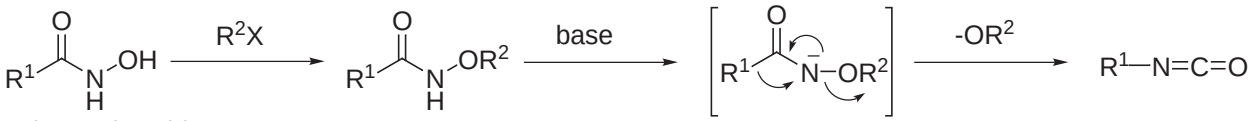


Houff *J. Org. Chem.* **1957**, *22*, 344.

5. Lossen Rearrangement

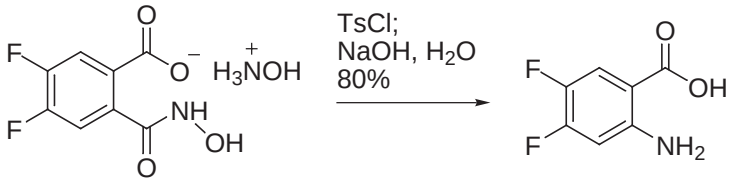
Lane *Org. React.* **1946**, *3*, 269 and 366.
Comprehensive Org. Syn., Vol. 6, pp 821-823 (basic conditions)
pp 824-825 (neutral/acidic)

Lossen *Liebigs Ann. Chem.* **1872**, *161*, 347.

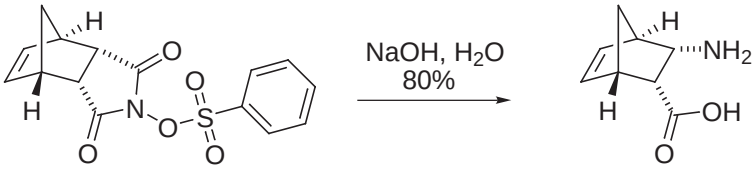


Hydroxamic acid
-prepared readily from carboxylic acids, esters or acyl halides

- R^2X usually AcCl, $ArSO_2Cl$, RPO_2Cl
- rate of reaction proportional to the acidity of leaving group conjugate acid
- R^1 migrates with retention of configuration

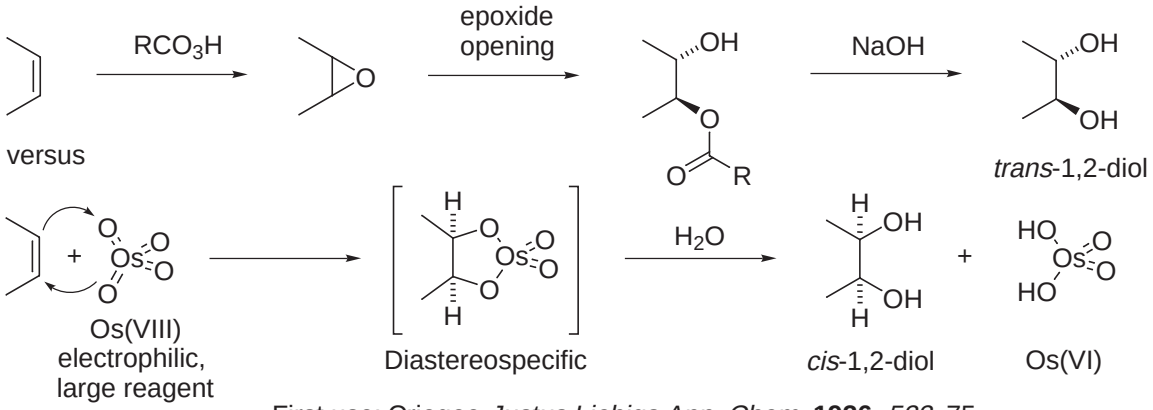


Braish *Syn. Commun.* **1992**, *22*, 3067.



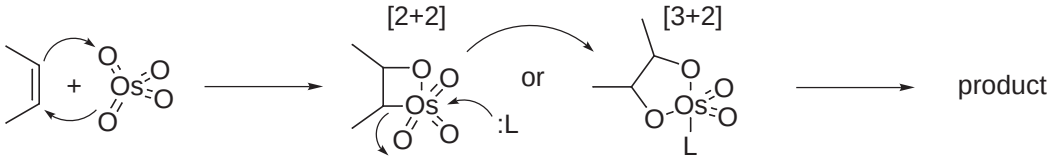
Bauer *J. Org. Chem.* **1959**, *24*, 1293.

G. Olefin Osmylation (Dihydroxylation)



First use: Criegee *Justus Liebigs Ann. Chem.* **1936**, *522*, 75.
Milas *J. Am. Chem. Soc.* **1936**, *58*, 1302.

1. Mechanism



[2 + 2] Mechanism:

Sharpless *J. Am. Chem. Soc.* **1977**, *99*, 3120.
Jorgensen *Chem. Rev.* **1990**, *90*, 1483.
Sharpless *Angew. Chem. Int. Ed. Eng.* **1993**, *32*, 1329.

[3 + 2] Mechanism:

Böseken *Recl. Trav. Chim.* **1922**, *41*, 199.
Criegee *Angew. Chem.* **1938**, *51*, 519.
Criegee *Justus Liebigs Ann. Chem.* **1942**, *550*, 99.

2. Scope *Comprehensive Org. Syn.,* Vol. 7, pp 437-448. *Chem. Rev.* **1980**, *80*, 187.

1. OsO_4 is an electrophilic reagent, and it behaves as a large reagent.
2. Strained, unhindered olefins react faster than unstrained, sterically hindered olefins.
3. Electron-rich olefins react faster than electron-deficient olefins.
4. Diastereospecific, with attack on the C=C from the least hindered face.

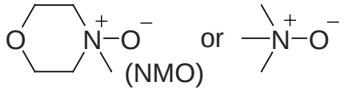
- but OsO_4 is expensive, volatile, and toxic

-various improvements: 1) only catalytic amount of OsO_4 used
2) use of an equivalent osmium salt ($K_2OsO_2(OH)_4$)

Examples:

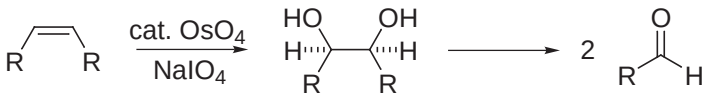
H_2O_2, cat. OsO_4 *J. Am. Chem. Soc.* **1936**, *58*, 1302; **1937**, *59*, 2345; *Synthesis* **1989**, 295.

^{t}BuOOH, cat. OsO_4 Sharpless *J. Org. Chem.* **1978**, *43*, 2063.



Tetrahedron Lett. **1976**, 1973;
Tetrahedron Lett. **1980**, *21*, 449.

Note: Johnson-Lemieux Oxidation ($NaIO_4$ and catalytic OsO_4 cleaves C=C bonds, forms diol and then aldehyde: *J. Org. Chem.* **1956**, *21*, 478).



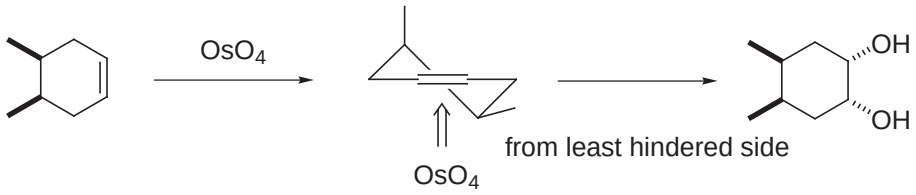
-Alternative reagents to OsO_4:

$KMnO_4$: *Synthesis* **1987**, 85.
Yields rarely as high as OsO_4 but less hazardous and less expensive especially for large scale

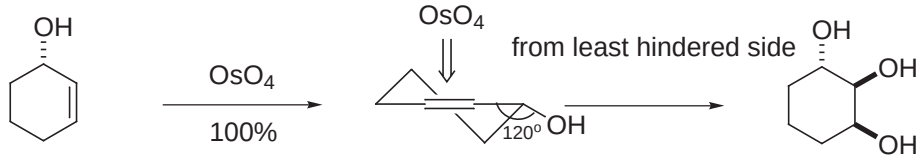
RuO_4 or RuO_2-$2H_2O$/$RuCl_3$-H_2O + cooxidant
More vigorous than OsO_4 and olefin cleavage is observed

3. Diastereoselectivity

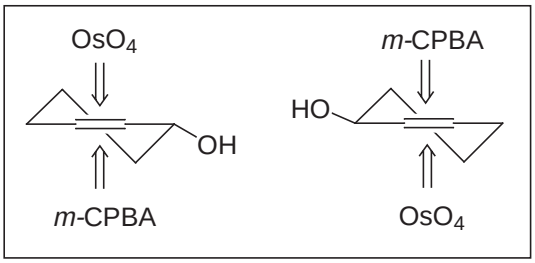
a. Endocyclic Olefins

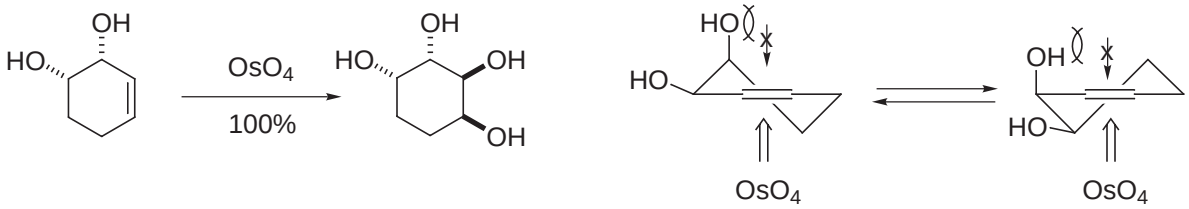


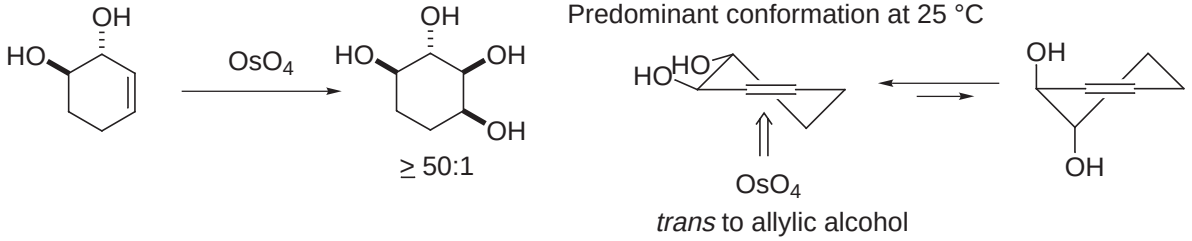
-endocyclic allylic alcohols

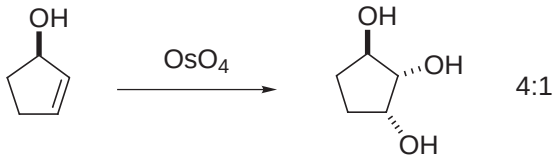


Note: *m*-CPBA comes in *cis* to the allylic -OH, but OsO_4 comes in *trans* to the allylic -OH.
So, we obtain:



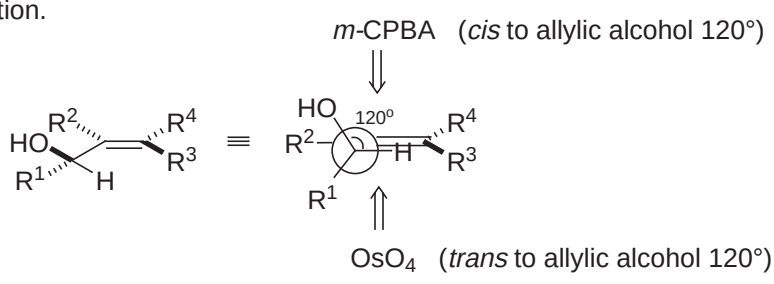




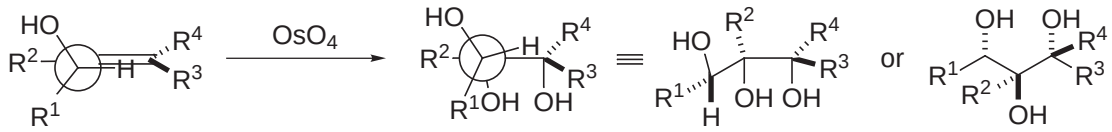


b. Acyclic Systems

- OsO_4 is delivered from face opposite the allylic hydroxyl group in the preferred (H-eclipsed) ground state conformation.

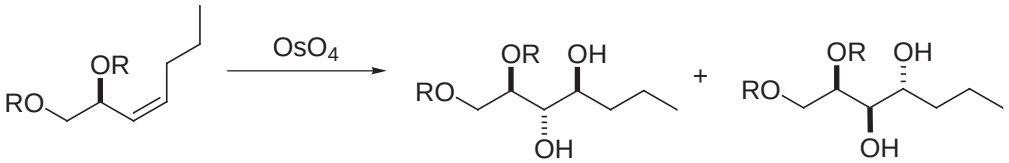


- Kishi model (empirical model). *Tetrahedron Lett.* **1983**, *24,* 3943, 3947.
  So, for the OsO_4 oxidation: *Tetrahedron* **1984**, *40*, 2247.



- Preferred ground state conformation (higher diastereoselection when R^3 is not H).

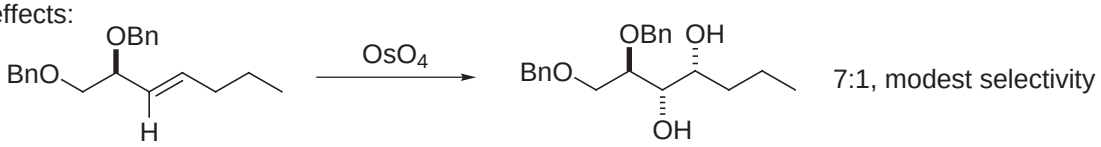
- Also observed with allylic ethers



1) electronic effects:	R = Bn	8.9	:	1
	R = CO_2CH_3	2	:	1
	R = COC_6H_4-NO_2	1	:	1

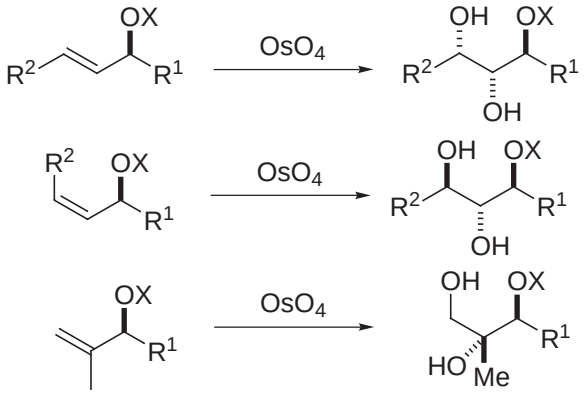
electronic effect of alkoxy substituent directs osmylation to reverse face

2) steric effects:



7:1, modest selectivity

- Higher diastereoselectivity of *Z* vs. *E* isomer implies eclipsed conformation important.



< 8:1, modest selectivity
(anti 1,2-diol relationship)

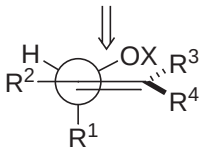
high selectivity

moderate to high selectivity

- As R^1 increases in size relative to OX, the selectivity increases.
- X-effect (steric effect): smaller X provides better selectivity.

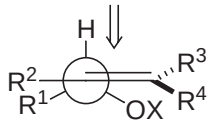
- There are two additional empirical models used to explain the acyclic allylic alcohol induced diastereoselectivity:

1. Houk Model (inside alkoxy model):
Science **1981**, *231*, 1108.



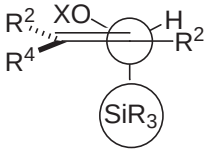
non ground state conformation

2. Vedejs Model:
J. Am. Chem. Soc. **1989**, *111*, 6861.



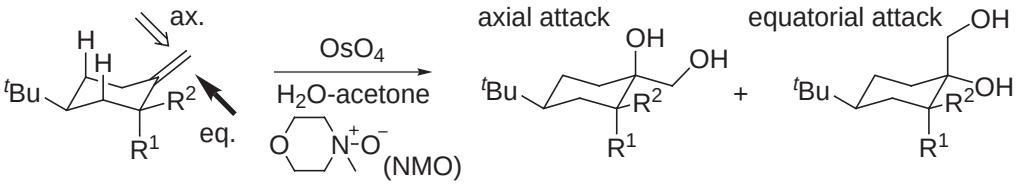
OsO_4 is large reagent; steric effects between reagent & allylic substituent are important factors

3. Panek:
J. Am. Chem. Soc. **1990**, *112*, 4873.



selectivity increases:
a) OH > OR
b) now *E* > *Z*
c) with very large R^1: inside alkoxy or anti Si

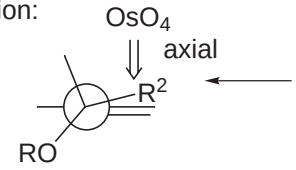
c. Exocyclic Olefins: Vedejs *J. Am. Chem. Soc.* **1989**, *111*, 6861.



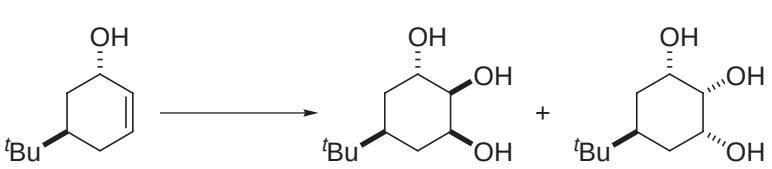
OsO_4 is a large reagent, prefers equatorial attack

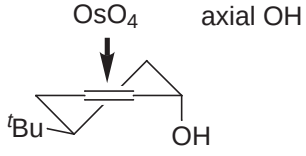
R^1	R^2	ax.	eq.	
H	H	14	86	Consistent with Kishi empirical model
H	OH	<5	95	Inconsistent with Houk model
H	OCH_3	<5	95	
CH_3	OCH_3	20	80	
H	OAc	8	92	
H	SCH_3	<5	95	
OH	H	33	67	H-bonding?
OH	CH_3	14	86	
OCH_3	H	88	12	Equatorial attack predominates,
OCH_3	CH_3	90	10	except with axial OCH_3, OAc, SMe:
OAc	CH_3	67	33	In these cases, equatorial attack further
SCH_3	H	92	8	retarded and proceeds at even slower rate (kinetic studies)

Exception:



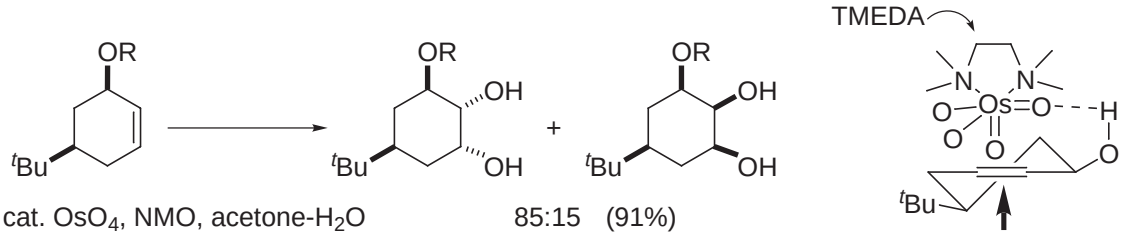
d. H-Bonding and Directed Dihydroxylation



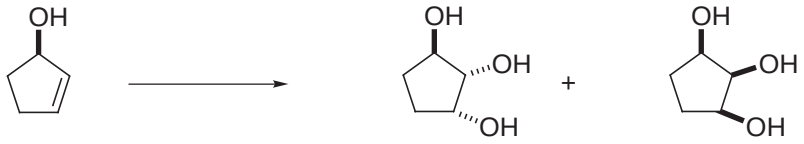


cat. OsO_4, NMO, acetone-H_2O	94:6	(90%)
1 equiv OsO_4, CH_2Cl_2 (anhydrous)	75:25	(97%)

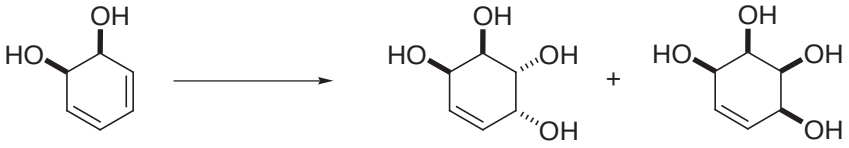
competing H-bonding delivery reduces diastereoselectivity



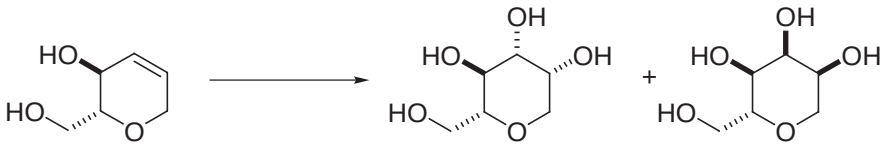
R = H:	cat. OsO_4, NMO, acetone-H_2O	85:15	(91%)	
	1 equiv OsO_4, CH_2Cl_2	63:37	(45%)	competing H-bond delivery
	cat. OsO_4, Me_3NO, CH_2Cl_2	45:55	(55%)	competing H-bond delivery
	1 equiv OsO_4, TMEDA, CH_2Cl_2, –78 °C	4:96	(91%)	← H-bond delivery
R = CH_3:	1 equiv OsO_4, CH_2Cl_2	95:5		← no H-bonding



cat. OsO_4, NMO, acetone-H_2O	80:20		
1 equiv OsO_4, TMEDA, CH_2Cl_2, –78 °C	12:88	(76%)	← H-bond delivery



cat. OsO_4, NMO, acetone-H_2O	75:25		
1 equiv OsO_4, TMEDA, CH_2Cl_2, –78 °C	5:95	(54%)	← H-bond delivery



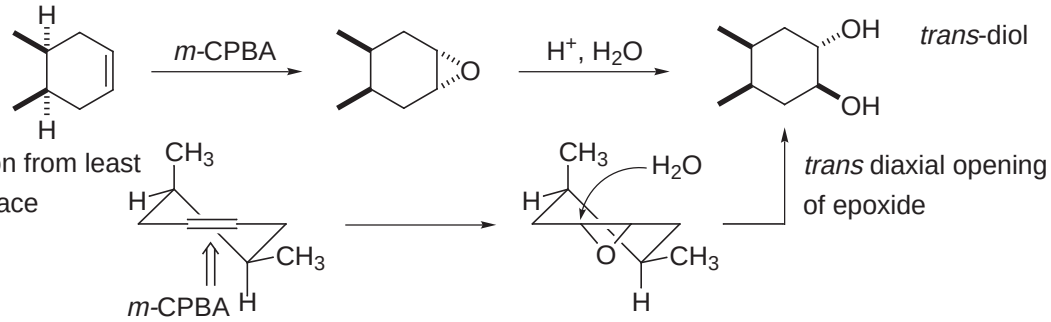
cat. OsO_4, NMO, acetone-H_2O	94:6		
1 equiv OsO_4, TMEDA, CH_2Cl_2, –78 °C	14:86	(63%)	← H-bond delivery

- OsO_4-TMEDA can also be utilized to effect chemoselectivity by preferentially oxidizing allylic alcohols over unactivated (non allylic -OH) double bonds.

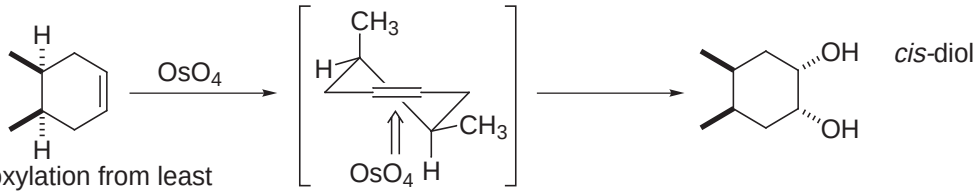
Donohue *Tetrahedron Lett.* **1996**, *37*, 3407; *Tetrahedron Lett.* **1997**, *38*, 5027.

4. Comparison of Diol Stereochemistry Generated by Different Methods

a. *m*-CPBA

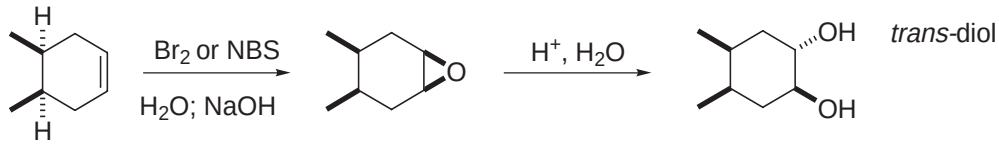


b. OsO_4

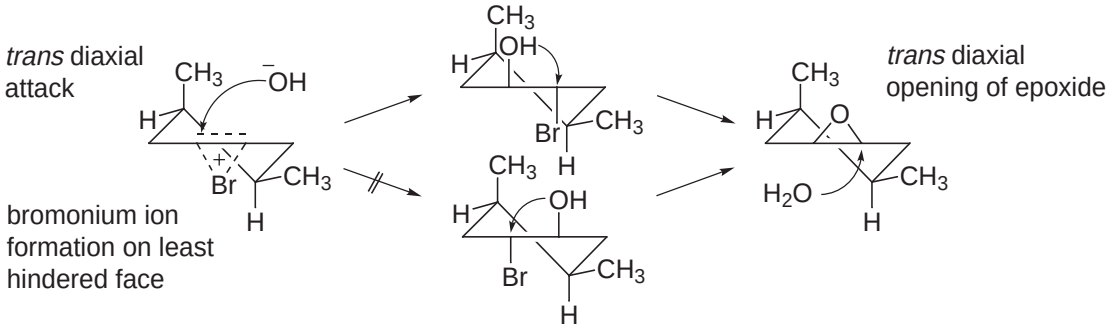


- *cis* dihydroxylation from least hindered face (OsO_4 is a large reagent)

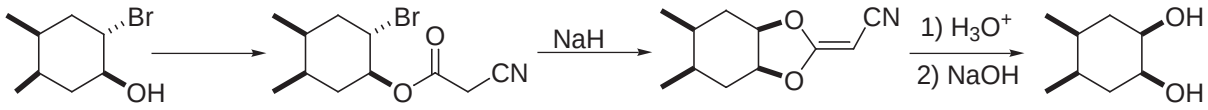
c. Via Bromohydrin



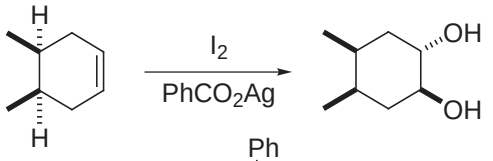
- Epoxidation on most hindered face of olefin (to give different epoxide from *m*-CPBA oxidation), *trans* diaxial ring opening (to give same hydrolysis product as from *m*-CPBA oxidation)



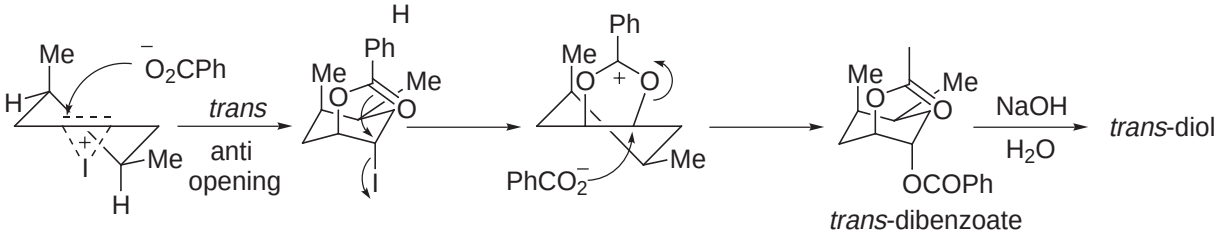
- Corey *Tetrahedron Lett.* **1982**, *23*, 4217: *cis* dihydroxylation from most hindered olefin face.



d. Prevost
Compt. rend. **1933**, *196*, 1128.

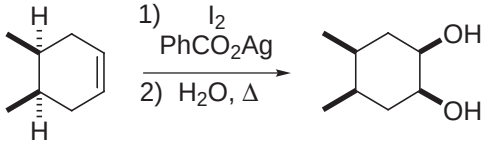


- Neighboring Group Participation

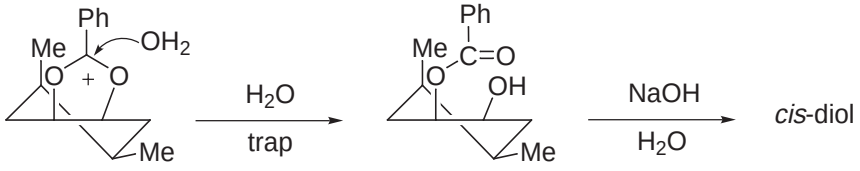


trans-dibenzoate

e. Woodward
J. Am. Chem. Soc. **1958**, *80*, 209.



- Complements OsO_4 reaction (i.e. *cis* dihydroxylation from most hindered face)



- Same intermediate as Prevost, but different conditions (+ H_2O)

H. Asymmetric Dihydroxylation Reaction Catalyzed by OsO_4 and Related Reagents

1. Catalytic Methods

Sharpless Catalytic Asymmetric Dihydroxylation (AD) Reaction, Review: *Chem. Rev.* **1994**, *94*, 2483.

J. Am. Chem. Soc. **1980**, *102*, 4263.

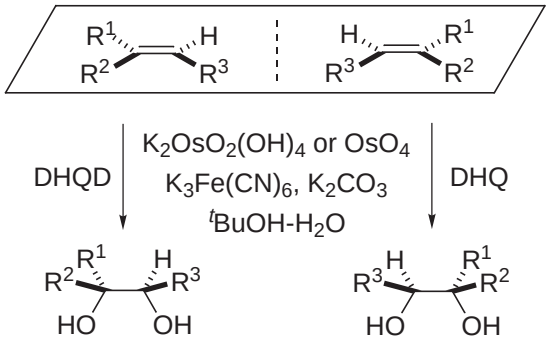
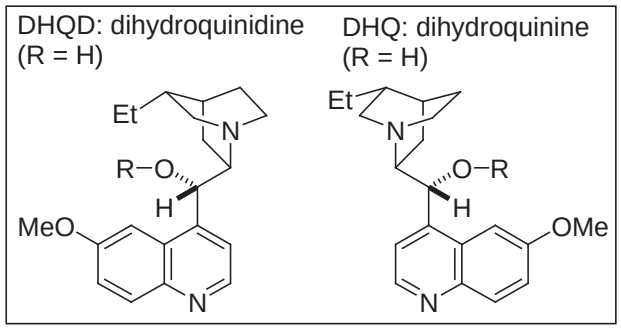
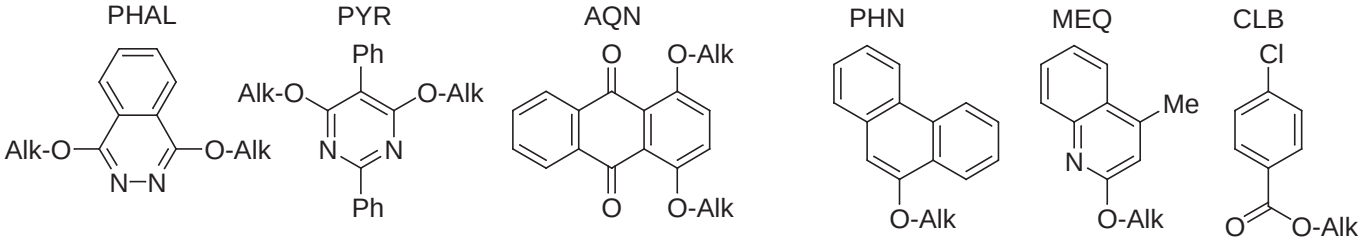
Tetrahedron Lett. **1993**, *34*, 7375.
J. Org. Chem. **1993**, *58*, 3785
J. Am. Chem. Soc. **1994**, *116*, 1278.
Angew. Chem., Int. Ed. Eng. **1996**, *35*, 448.





Second Generation Ligands (Alk = DHQ or DHQD)



First Generation Ligands (Alk = DHQ or DHQD)

Catalyst: OsO_4 (1.25 mol%) or $K_2OsO_2(OH)_4$ (0.05 mol%, nonvolatile)
Solvent: ^{t}BuOH or cyclohexane, H_2O, K_2CO_3
Ligands: DHQD or DHQ (0.2 to 0.004 mol%)
Oxidant to recycle OsO_4: $K_3Fe(CN)_6$

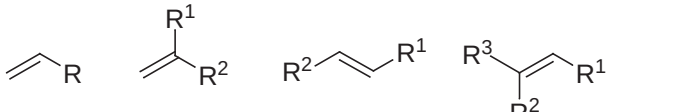
Note: **Ligand accelerated catalysis**, Sharpless *Angew. Chem., Int. Ed. Eng.* **1995**, *34*, 1059.

-Addition of pyr led to marked increase in rate of formation of cyclic osmate ester from alkene and OsO_4. First noted by Criegee *Justus Liebigs Ann. Chem.* **1936**, *522*, 75; **1940**, *550*, 99.

-The "Criegee effect" (or the facilitation of osmylation step by nitrogen donor) has been examined with quinuclidine and cinchona alkaloid ligands: Sharpless *J. Am. Chem. Soc.* **1994**, *116*, 1278, 8470.

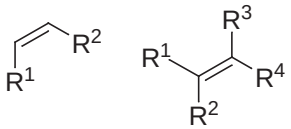
-Results:

Good to excellent selectivity (ee%) for:



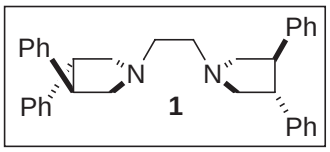
74-93% ee 82-88% ee 94-99% ee 84-93% ee

Poor selectivity for:

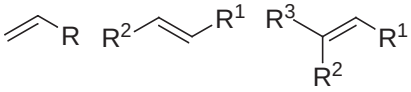


2. Stoichiometric methods

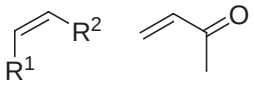
-Tomioka *J. Am. Chem. Soc.* **1987**, *109*, 6213.



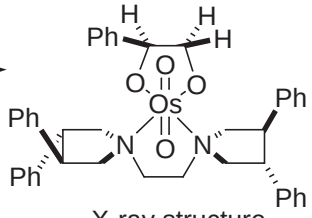
Using **1** as a chiral ligand, good selectivity for:



Poor selectivity for:



- Product does not seem to reflect most favorable steric approach for [3 + 2] cycloaddition but is more easily rationalized by [2 + 2].



X-ray structure

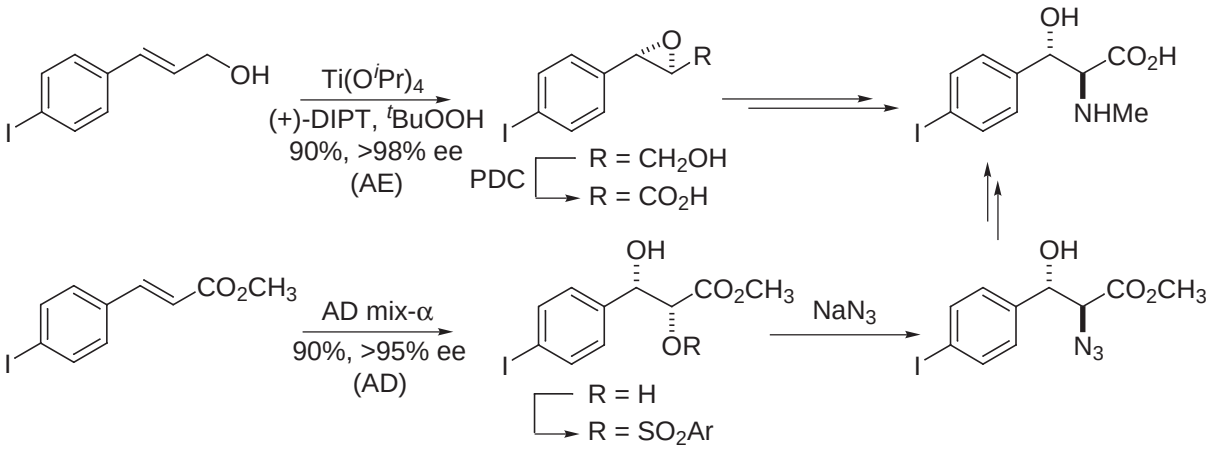
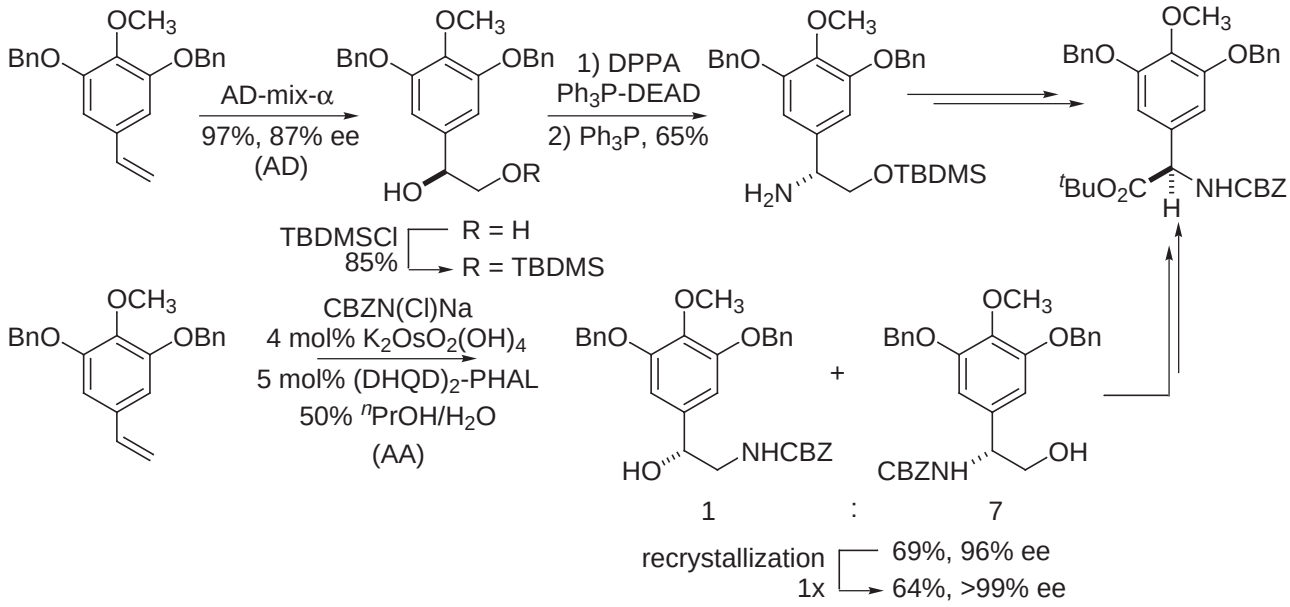
3. Examples

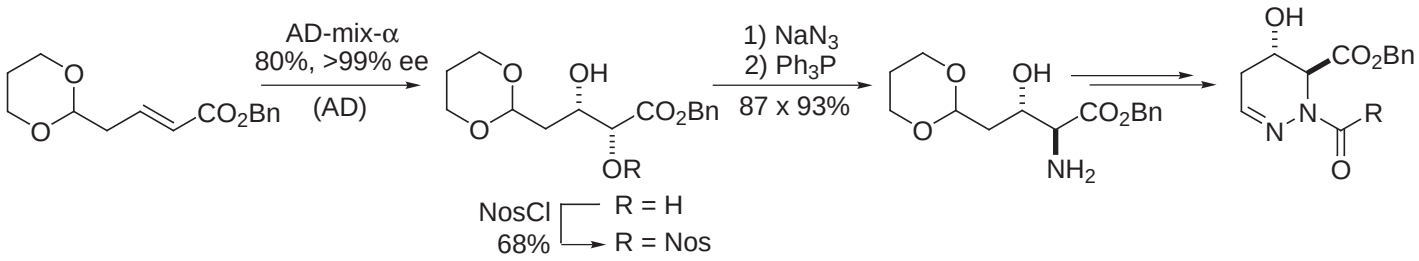
-Total synthesis of Bouvardin and RA-VII: Boger *J. Am. Chem. Soc.* **1994**, *116*, 8544.



-Vancomycin central amino acid: Boger *J. Org. Chem.* **1996**, *61*, 3561; *J. Org. Chem.* **1997**, *62*, 4721.

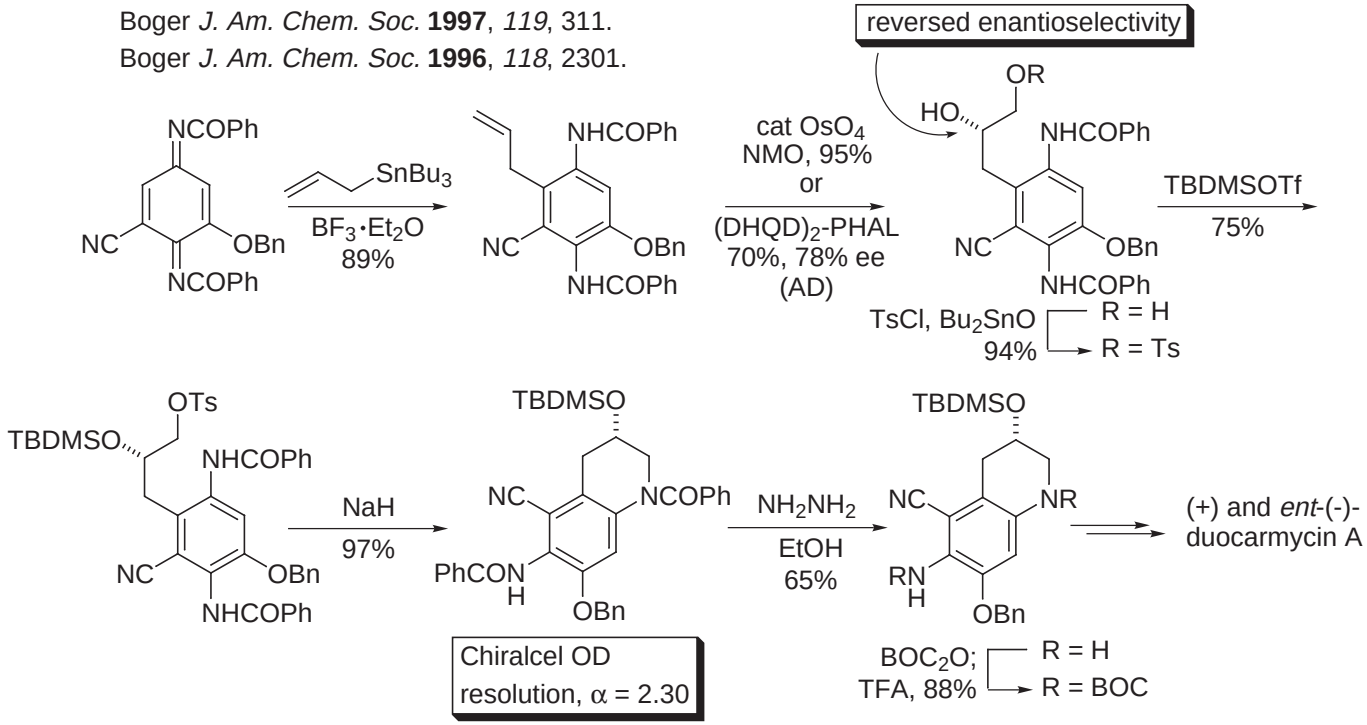


-Luzopeptin Htp amino acid: Boger *J. Org. Chem.* **1998**, *63*, 6421; *J. Am. Chem. Soc.* **1999**, *121*, 1198.



-Prediction of absolute stereochemistry is so firmly documented that it may be used to assign absolute stereochemistry. However, there are a few rare exceptions to be aware of, for example:

Boger *J. Am. Chem. Soc.* **1997**, *119*, 311.
Boger *J. Am. Chem. Soc.* **1996**, *118*, 2301.



-Appears to be general for the class of olefins $ArCH_2CH{=}CH_2$

I. Sharpless Catalytic Asymmetric Aminohydroxylation (AA)

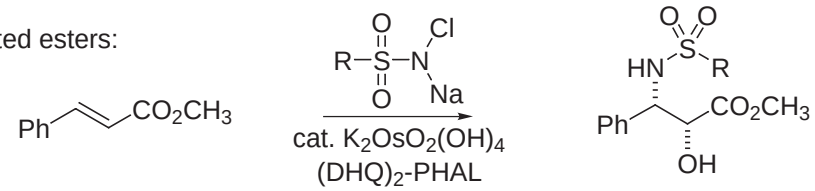
- Reviews: *Transition Metals for Fine Chemicals and Organic Synthesis*; Beller, M., Bolm, C., Eds.; Wiley-VCH: Weinheim, **1998**.

Angew. Chem. Int. Ed. Eng. **1996**, *35*, 451, 2810 and 2813. *J. Am. Chem. Soc.* **1998**, *120*, 1207.
Angew. Chem. Int. Ed. Eng. **1997**, *36*, 1483 and 2637. *Tetrahedron Lett.* **1998**, *39*, 2507 and 3667.

- Development of AA reaction (reactions generally run with 4 mol% catalyst ($K_2OsO_2(OH)_4$) and 5 mol% ligand ($(DHQ)_2$-PHAL or $(DHQD)_2$-PHAL): *in situ* generation and reactions of $RN{=}OsO_3$.

a. Sulfonamide variant

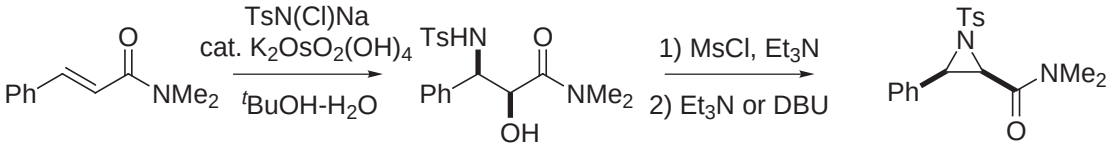
-α,β-unsaturated esters:



R =				
	p-Tol	1:1 CH_3CN-H_2O	81% ee (64%)	Reductive cleavage of sulfonamides requires harsh conditions (Birch reduction, Red-Al, or 33% HBr/AcOH).
	Me	1:1 ^{n}PrOH-H_2O	95% ee (65%)	
		1:1 ^{n}PrOH-H_2O	70% ee (48%) ← Sulfonamide cleaved with Bu_4NF in CH_3CN	

83:17 regioselectivity

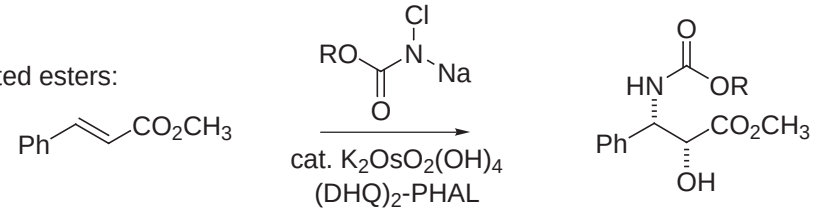
-α,β-unsaturated amides: no enantioselection, AA gives racemic products.
-reaction works well without a ligand.



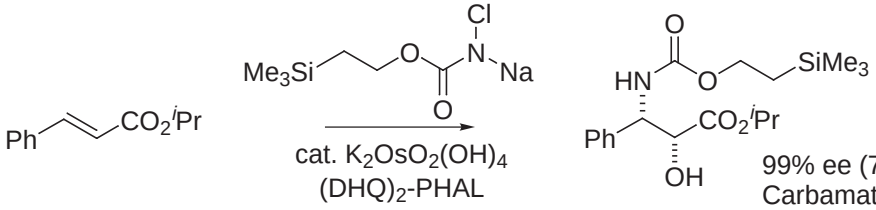
5:1 regioselectivity, racemic (94%)

b. Carbamate variant

-α,β-unsaturated esters:

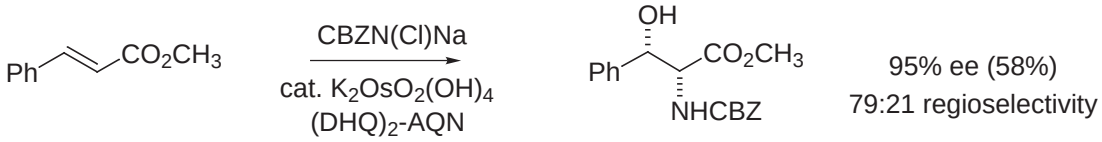


R =				
	Bn	1:1 ^{n}PrOH-H_2O	94% ee (65%) ←	Amine can be deprotected by hydrogenolysis.
	Et	1:1 ^{n}PrOH-H_2O	99% ee (78%)	
	^{t}Bu	2:1 ^{n}PrOH-H_2O	78% ee (71%) ←	Amine can be deprotected by acid.



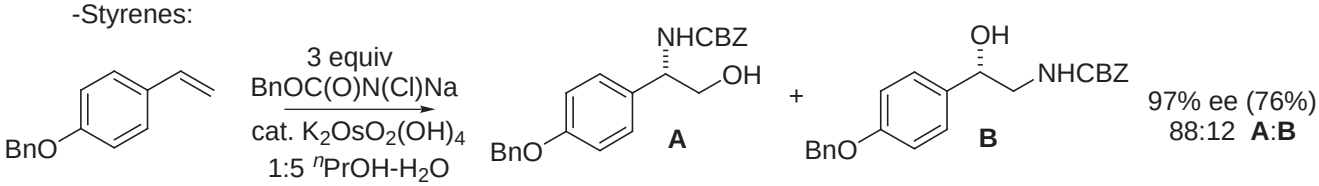
99% ee (70%)
Carbamate cleaved with Bu_4NF in CH_3CN.

-Reversal of regioselectivity using $(DHQ)_2$-AQN ligand



95% ee (58%)
79:21 regioselectivity

-Styrenes:



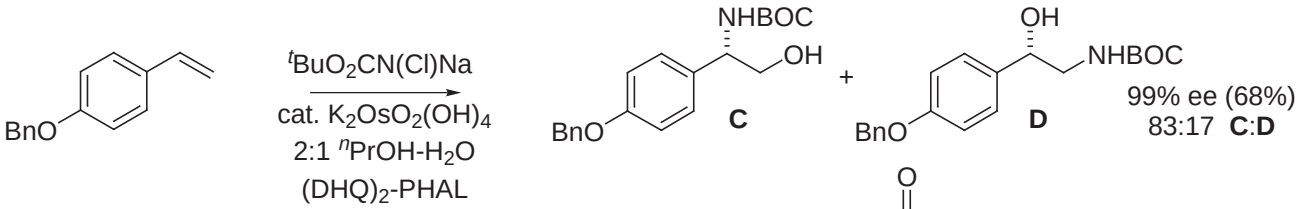
97% ee (76%)
88:12 **A**:**B**

-Influence of ligand and solvent on regioselectivity:

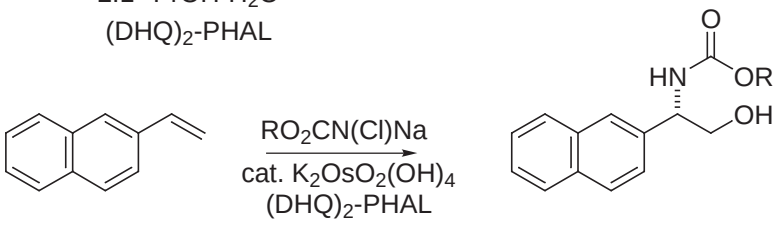
ligand	solvent	**A:B**
$(DHQ)_2$-PHAL	^{n}PrOH-H_2O	88:12
$(DHQ)_2$-AQN	CH_3CN-H_2O	25:75

- However, enantioselectivities for **B** regioisomers are poor (0-80% ee).

- ^{t}Bu carbamate based AA affords slightly poorer regioselectivities and yields compared to benzyl carbamate series, but enantioselectivities approach 100% in both cases:



99% ee (68%)
83:17 **C**:**D**



R =			
	Bn	99% ee (70%)	>10:1 regioselectivity
Me$_3$Si	^{t}Bu	98% ee (70%)	88:12 regioselectivity
		97% ee (48%)	86:14 regioselectivity

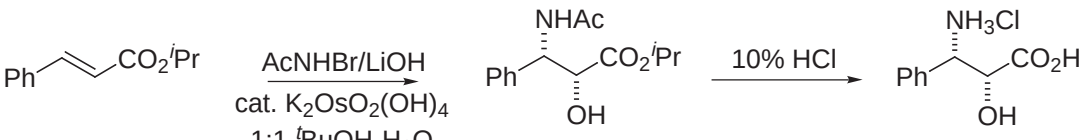
of regioisomers

c. Amide variant



99% ee, 81%
(>10:1 regioselectivity)

77% overall

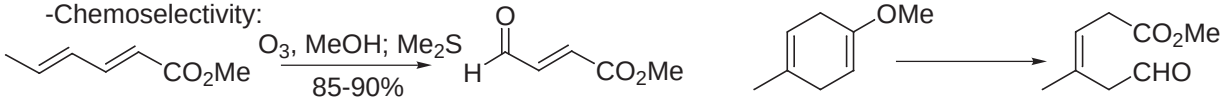
J. Ozonolysis

Comprehensive Org. Syn., Vol. 7, pp 541-591.

P. Crutzen, M. Molina, and F. S. Rowland shared the 1995 Nobel Prize in Chemistry for their work in atmospheric chemistry, particularly concerning the formation and decomposition of the protective ozone layer.

-Electrophilic reagent, rate: electron-rich > neutral > electron-deficient olefin

-Chemoselectivity:



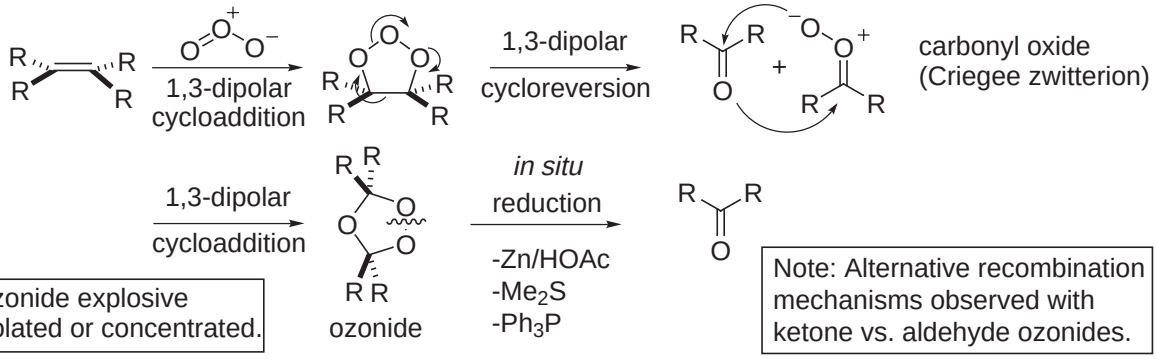
-O_3 exhibits very light blue color, ozonolysis complete when color persists

-Controlled ozonolysis (very reactive agent): KI-starch: characteristic blue color
O_3 sensitive dyes with varying reactivities and detect color disappearance: Mitscher *Synthesis* **1980**, 807.

-Oxidative workup: H_2O_2, $KMnO_4$, Cr(VI), RuO_4 -> ketones, carboxylic acids

-Reductive workup: $NaBH_4$, $LiBH_4$ -> alcohols
Me_2S, Ph_3P, Zn/HOAc, $H_2N(C=S)NH_2$, H_2, $Pd/CaCO_3$ -> aldehydes, ketones

-Mechanism, Review: Criegee *Angew. Chem., Int. Ed. Eng.* **1975**, *14*, 745.



Note: Ozonide explosive when isolated or concentrated.

Note: Alternative recombination mechanisms observed with ketone vs. aldehyde ozonides.

V. Oxidation of Alcohols

Comprehensive Org. Syn., Vol. 7, pp 251-327.

Stoichiometries:

$$3\ R_2CHOH + 2\ CrO_3 + 6\ H^+ \longrightarrow 3\ R_2C{=}O + 2\ Cr^{3+} + 6\ H_2O$$

$$5\ R_2CHOH + 2\ MnO_4^- + 6\ H^+ \longrightarrow 5\ R_2C{=}O + 2\ Mn^{2+} + 8\ H_2O$$

$$3\ R_2CHOH + 2\ MnO_4^- \longrightarrow 3\ R_2C{=}O + 2\ Mn^{2+} + 2\ H_2O$$

A. Chromium-based Oxidation Reagents

1. Collins Reagent: Collins *Tetrahedron Lett.* **1968**, 3363; *Org. Syn.* **1972**, *52*, 5.

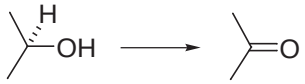
-CrO_3-pyr_2, alkaline oxidant

-Hygroscopic, red crystalline complex

-Can also be isolated and stored, but usually generated *in situ* by CrO_3 + pyr (**Sarett Reagent**)
J. Am. Chem. Soc. **1953**, *75*, 422. Note: Add CrO_3 to pyr, not pyr to CrO_3 (inflames)

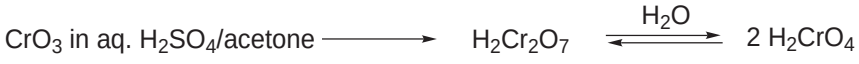
-Good for acid sensitive substrates

-**Radcliffe modification:** *in situ* preparation and use in CH_2Cl_2, *J. Org. Chem.* **1970**, *35*, 4000.



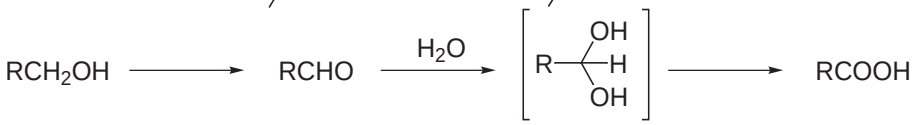
$RCH_2OH \longrightarrow RCHO \not\longrightarrow RCOOH$
no over oxidation

2. Jones Reagent: Jones *J. Chem. Soc.* **1953**, 2548; *J. Chem. Soc.* **1946**, 39.



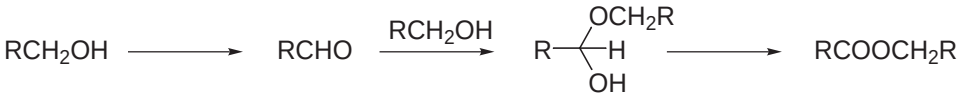
-Acetone solvent serves to protect substrate from over oxidation

-Not good for oxidations of acid sensitive substrates



-Acidic oxidation conditions, H^+ catalyzed reactions possible

-Another common side reaction for primary alcohol oxidation:



Solution: run under dilute reaction conditions to circumvent esterification

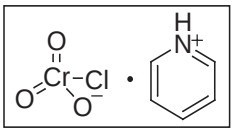
hemiacetal

ester

-**Brown oxidation**: run under two phase reaction conditions, Et_2O-H_2O, *J. Org. Chem.* **1971**, *36*, 387.

-$[R_4N]_2Cr_2O_7$ *Synth. Commun.* **1980**, 75. Oxidation of allylic/benzylic alcohols under neutral conditions.

3. Pyridinium Chlorochromate (PCC): Corey and Suggs *Tetrahedron Lett.* **1975**, 2647.

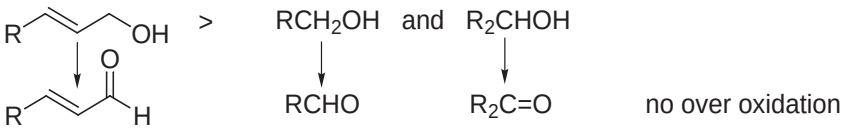


HCl + CrO_3 + pyr

- Chloride facilitates formation of chromate ester (slow step in oxidation reaction)
- Stable, commercially available reagent

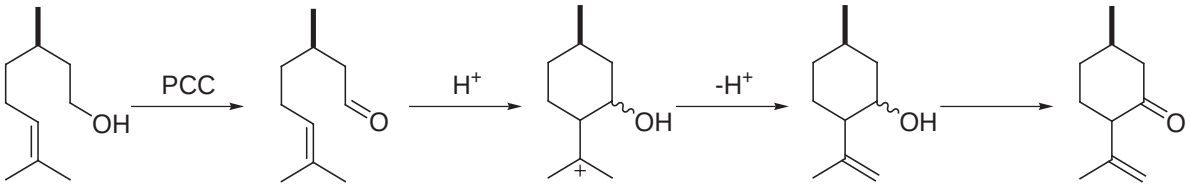
-Reaction usually carried out in CH_2Cl_2

-Rates:

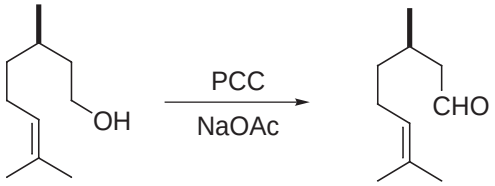


-Usually only need 1-2 equiv of Cr(VI) reagent (Jones & Collins usually require 6 equiv)

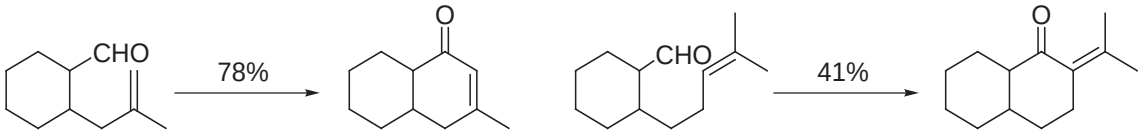
-PCC slightly acidic which can cause side reactions, for example:

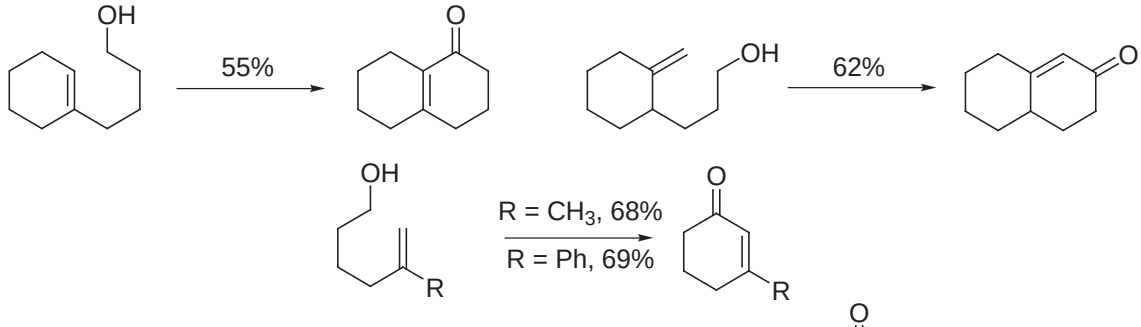


-To avoid H^+ catalyzed side reaction, use sodium acetate buffer:

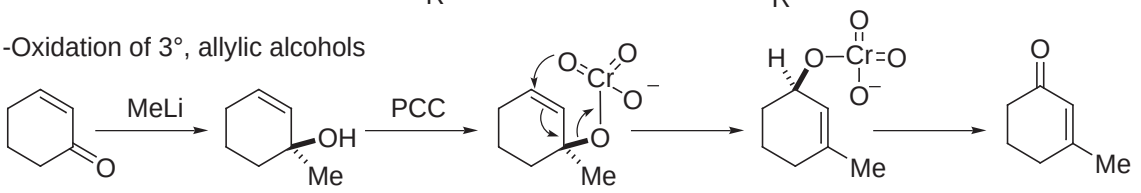


-Can take advantage of acidity in PCC reaction (Boger and Corey *Tetrahedron Lett.* **1978**, 2461):





-Oxidation of 3°, allylic alcohols



[3,3]-sigmatropic rearrangement, Dauben *J. Org. Chem.* **1977**, *42*, 682.

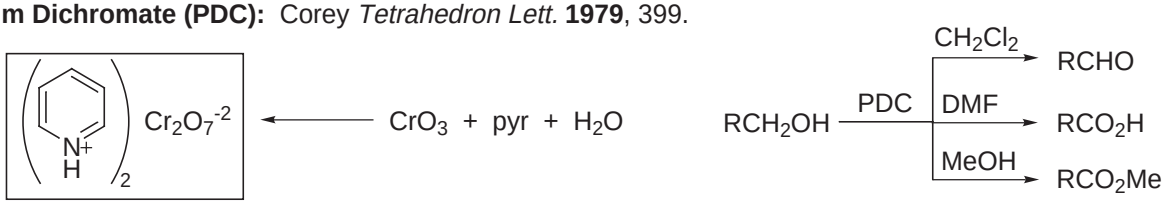
-Aromatic amine effect: dampens reactivity so only selective oxidation of allylic alcohols may be observed

PCC, pyr (2%) in CH_2Cl_2	*Chem. Phys. Lipids* **1980**, *27*, 281.
PCC, 3,5-dimethylpyrazole (2%) in CH_2Cl_2	*J. Org. Chem.* **1983**, *48*, 4766.
PCC, benzotriazole (2%) in CH_2Cl_2	*Synth. Commun.* **1985**, *15*, 393.
-3 Å MS accelerate rate of oxidation (PCC and PDC)	*J. Chem. Soc., Perkin Trans. 1* **1982**, 1967.

-**Pyridinium fluorochromate**, related stable reagent that is slightly less acidic (Corey and Suggs)

-Other related reagents include bipyridinium chlorochromate (BPCC), DMAP chlorochromate, quinolinium chlorochromate, and pyrazinium chlorochromate.

4. Pyridinium Dichromate (PDC): Corey *Tetrahedron Lett.* **1979**, 399.



-Stable, commercially available reagent

-Not as acidic as PCC

-Oxidations slower than PCC or other oxidation reagents

-Can selectively oxidize 1° alcohols to aldehyde or carboxylic acid depending on solvent

-2° alcohols oxidize only slowly- sometimes require an acid catalyst (pyridinium trifluoroacetate or 3 Å MS)

-Note: Original reagent made in search of more acidic reagent, attempted preparation of pyridinium trifluoroacetyl chromate (Boger, Ph.D. dissertation, Harvard Univ., 1980).

-Other related reagents include nicotinium dichromate, quinolinium dichromate, and imidazolium dichromate

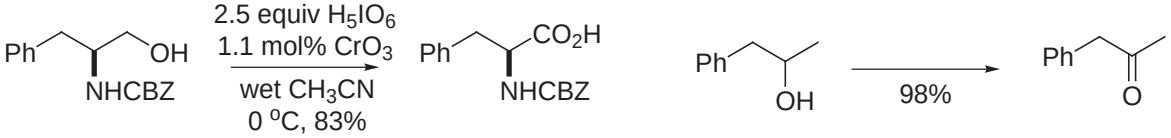
-Note: Cr based reagents will oxidize amines and sulfides. Substrates with these functional groups must be oxidized with other reagents (PDC will sometimes leave sulfides unaffected).

5. CrO_3-H_5IO_6: Zhao and Reider *Tetrahedron Lett.* **1998**, *39*, 5323.

-Catalytic in CrO_3 (1-2%, Industrial scale chromium-based oxidations)

-1° alcohols ⟶ carboxylic acids with no racemization

-2° alcohols ⟶ ketones



B. Manganese-based Oxidation Reagents

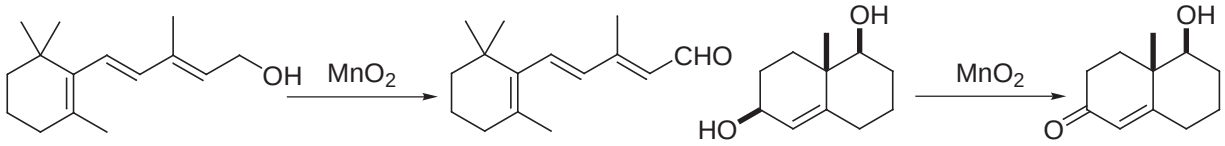
1. Manganese Dioxide (MnO_2)

-Very mild oxidizing reagent, special "activated" MnO_2 preparation required

-Selectively oxidizes allylic and benzylic alcohols to aldehyde or ketone

-Requires nonpolar solvent (CH_2Cl_2, $CHCl_3$, pentane, benzene, etc.)

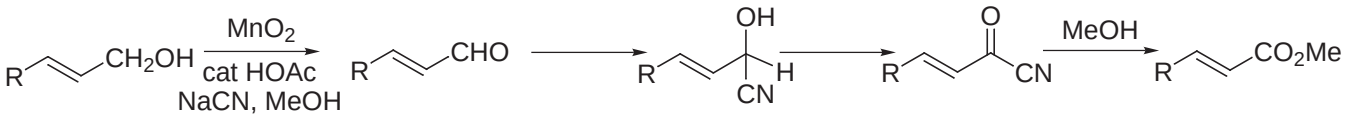
-Oxidizing reagent : substrate = 10:1 (10 wt. equiv)



-No isomerization of conjugated double bond. Cr-based reagent will cause problem due to H^+ catalysis

-NiO_2: alternative reagent that behaves similar to MnO_2

-Oxidize alcohol to ester, no isomerism of C=C bond (Corey and Ganem *J. Am. Chem. Soc.* **1968**, *90*, 5616)



2. $KMnO_4$

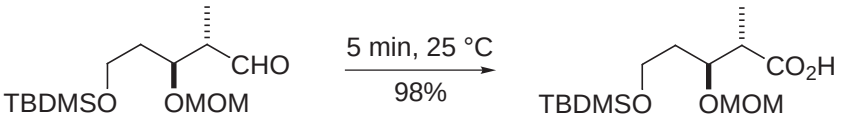
a. $KMnO_4/H_2SO_4$

-Good for $RCH_2OH \longrightarrow RCOOH$

-Reaction runs in aqueous solution because of the insolubility of $KMnO_4$ in organic solvents

b. $KMnO_4$ in ^{t}BuOH-5% NaH_2PO_4 aqueous buffer (Masamune *Tetrahedron Lett.* **1986**, *27*, 4537).

-For highly oxygenated systems where multiple side reaction pathways are present with other oxidants



3. R_4NMnO_4

-Same capabilities as $KMnO_4$ but soluble in organic solvents

4. $Cu(MnO_4)$-$6H_2O$ and $BaMnO_4$

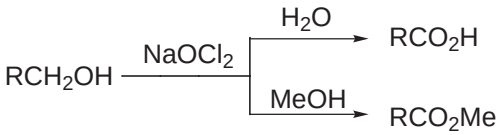
Lee *J. Am. Chem. Soc.* **1983**, *105*, 3188; *J. Org. Chem.* **1982**, *47*, 2790.
Hauser *J. Am. Chem. Soc.* **1984**, *106*, 1862.
Jefford *J. Chem. Soc., Chem. Commun.* **1988**, 634.
Hahn *Tetrahedron Lett.* **1989**, *30*, 2559.

C. Other Oxidation Reagents

1. RCH_2OH or R_2CHOH oxidation

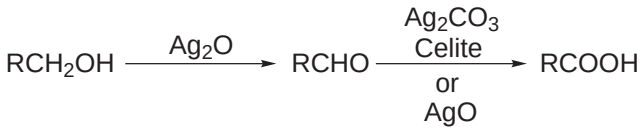
a. Sodium Hypochlorite (NaOCl): Used primarily to oxidize alcohols or aldehydes to carboxylic acids.

b. Sodium Chlorite ($NaOCl_2$) Pinnick *Tetrahedron* **1981**, *37*, 2091. Also Calcium Hypochlorite ($Ca(OCl)_2$): McDonald *Tetrahedron Lett.* **1993**, *34*, 2741.

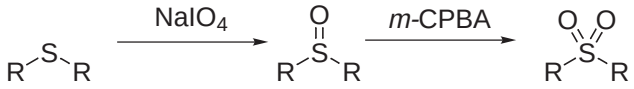


-Good for oxidation of sensitive aldehydes to carboxylic acids

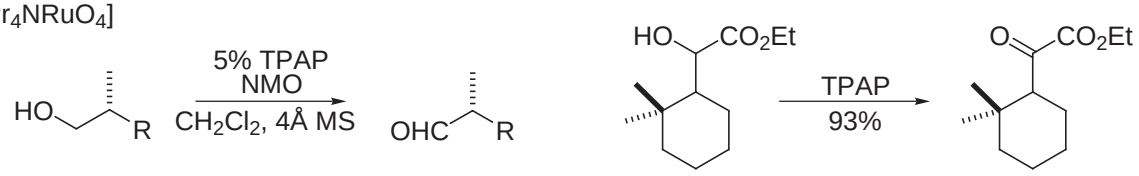
c. Ag_2O and Ag_2CO_3



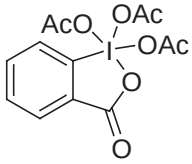
2. *m*-CPBA and $NaIO_4$ (Amine and sulfide oxidation)



3. TPAP, $[Pr_4NRuO_4]$

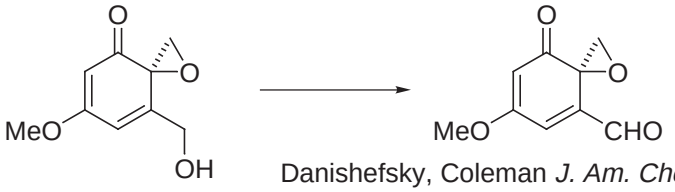


4. Dess-Martin Oxidation: Dess and Martin *J. Am. Chem. Soc.* **1978**, *100*, 300; *J. Am. Chem. Soc.* **1979**, *101*, 5294; *J. Org. Chem.* **1983**, *48*, 4155; *J. Am. Chem. Soc.* **1991**, *113*, 7277.

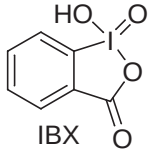


-periodinane
-CH_2Cl_2, 25 °C

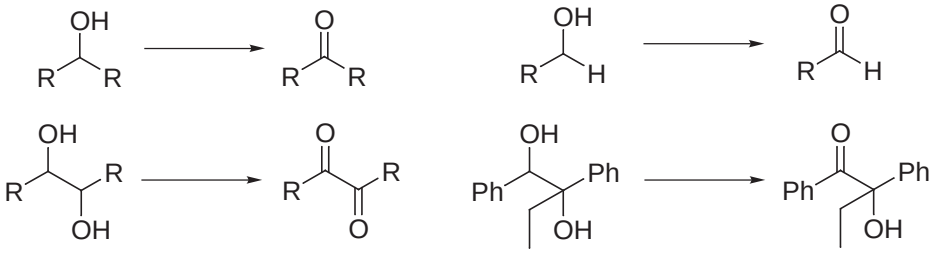
$RCH_2OH \longrightarrow RCHO$
$R_2CHOH \longrightarrow R_2C{=}O$



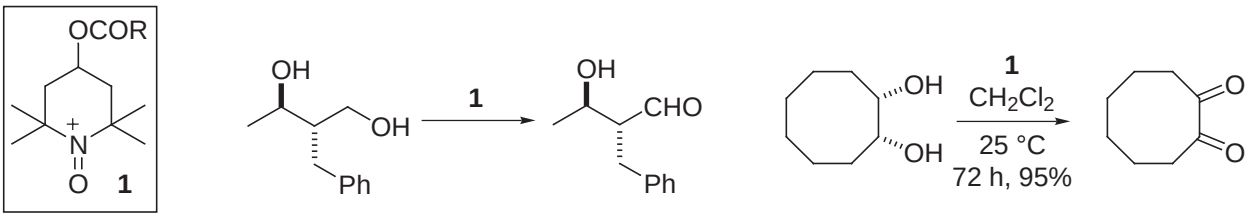
Danishefsky, Coleman *J. Am. Chem. Soc.* **1991**, *113*, 3850.



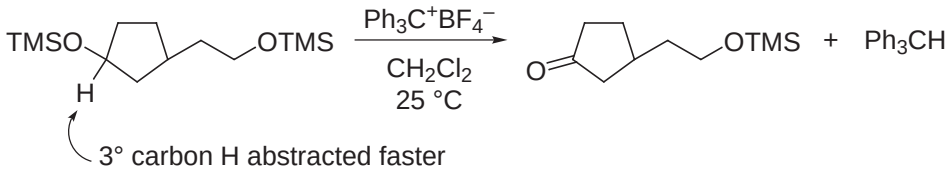
- Precursor to Dess-Martin reagent
- Insoluble in almost all organic solvents but is soluble in DMSO and oxidations in this solvent work effectively (25 °C): Frigerio *Tetrahedron Lett.* **1994**, *35*, 8019.



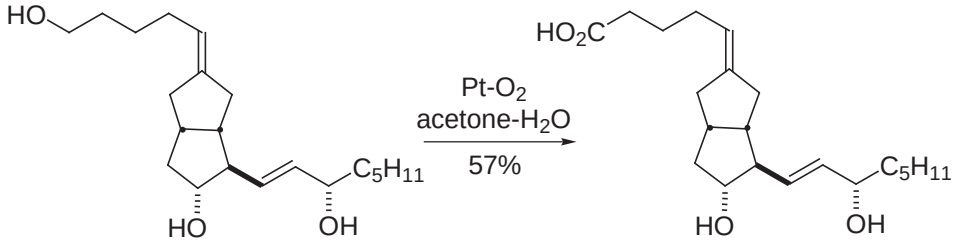
5. Nitroxide: Torii *J. Org. Chem.* **1990**, *55*, 462; Skarzewski *Tetrahedron Lett.* **1990**, *31*, 2177.



6. Trityl Cation: Jung *J. Am. Chem. Soc.* **1976**, *98*, 7882.



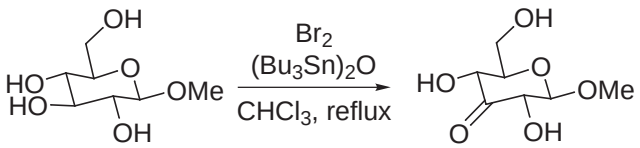
7. Pt-O_2: Fuchs and Hutchinson *J. Am. Chem. Soc.* **1987**, *109*, 4755.
-Good for oxidation of 1° alcohols directly to carboxylic acids



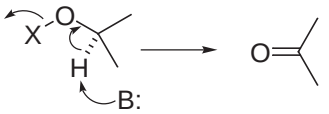
8. Via Hypohalite

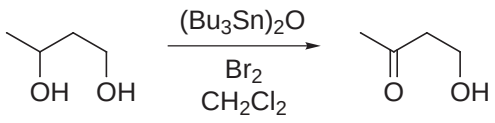
Just *Tetrahedron Lett.* **1980**, *21*, 3219.
Doyle *Tetrahedron Lett.* **1980**, *21*, 2795.
Nozaki *Tetrahedron Lett.* **1982**, *23*, 539.
Hannessian *Synthesis* **1981**, 394.
Kanemitsu *Chem. Pharm. Bull.* **1989**, *37,* 2394.
Stevens *Tetrahedron Lett.* **1982**, *23*, 4647.

-For example: $(Bu_3Sn)_2O$, Br_2 $NiBr_2$, $(PhCO_2)_2$ NIS, Bu_4NI $NaBrO_3$, CAN NaOCl, HOAc

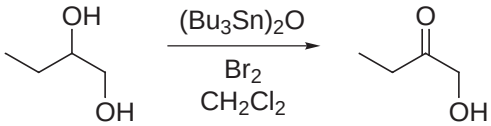


Mechanism:



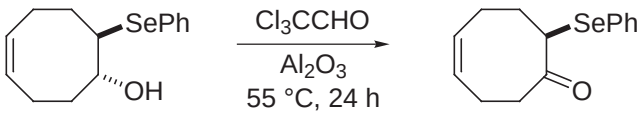


Tetrahedron Lett. **1976**, 4597.



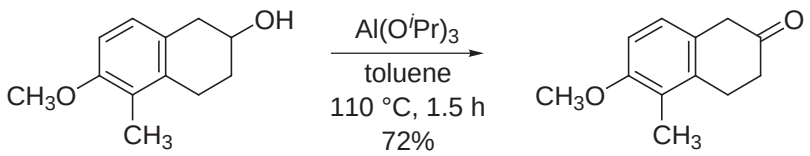
2° alcohol > 1° alcohol

9. Oppenauer Oxidation: see Meerwein-Pondorff-Verley reduction, Review: *Org. React.* **1951**, *6*, 207.



- Suitable for oxidation of 2° alcohol in the presence of 1° alcohol which do not react
- Good for oxidation of substrates containing easily oxidized functional groups

Posner *Angew. Chem., Int. Ed. Eng.* **1978**, *17*, 487; *Tetrahedron Lett.* **1977**, 3227; **1976**, 3499.



Boger *J. Org. Chem.* **1984**, *49*, 4045.

10. Ruthenium Tetroxide (RuO_4) $RCH_2OH \longrightarrow RCO_2H$ $R_2CHOH \longrightarrow R_2C{=}O$

-*in situ* generation from RuO_2-$NaIO_4$ or RuO_2-NaOCl: *Tetrahedron Lett.* **1970**, 4003.
J. Org. Chem. **1987**, *52*, 1149.

from $RuCl_3$-H_5IO_6: Sharpless *J. Org. Chem.* **1988**, *53*, 5187.
J. Org. Chem. **1981**, *46*, 3936.

-Note: RuO_4 attacks C=C bonds and will cleave 1,2-diols.

11. TEMPO

-with cat. NaOCl or $NaBrO_2$: *J. Org. Chem.* **1985**, *50*, 1332.
J. Org. Chem. **1987**, *52*, 2559.
J. Org. Chem. **1990**, *55*, 462.

RCH_2OH $\xrightarrow[\text{TEMPO}]{NaBrO_2}$ $\xrightarrow{MeCN}$ RCO_2H / $\xrightarrow{CH_2Cl_2}$ RCHO

-with cat. $Ca(OCl)_2$: Dess and Martin *J. Org. Chem.* **1983**, *48*, 4155.
Corey *J. Am. Chem. Soc.* **1996**, *118*, 1229.
Smith *J. Am. Chem. Soc.* **1989**, *111*, 5761.
Tetrahedron Lett. **1982**, 2335.

D. Swern Oxidation and Related Oxidation Procedures

1. Swern Oxidation: *J. Org. Chem.* **1976**, *41*, 957 and 3329.

Reviews: *Chem. Rev.* **1967**, *67*, 247.
Tetrahedron **1978**, *34*, 1651.
Synthesis **1981**, 165.
Org. React. **1990**, *34*, 297.

DMSO +   [DMSO-$(COCl)_2$]

DMSO + TFAA  [DMSO-TFAA]

-Also DMSO-Ac_2O, DMSO-SO_3/pyr, DMSO-$SOCl_2$, DMSO-Cl_2

2. Corey-Kim Oxidation: *Tetrahedron Lett.* **1974**, 287; *J. Am. Chem. Soc.* **1972**, *94*, 7586.

 [DMS-NCS]

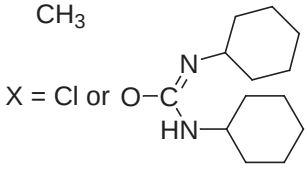
3. Moffatt-Pfitzner Oxidation (DCC-DMSO): *J. Am. Chem. Soc.* **1963**, *85*, 3027; *J. Am. Chem. Soc.* **1965**, *87*, 5670.

DMSO +   [DMSO-DCC]

-Mechanism:

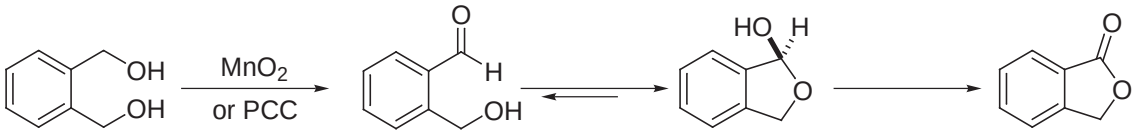
1. RCH_2OH +   + 
 + B:

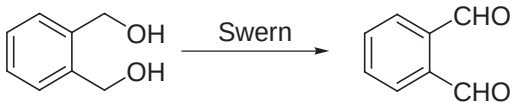
2. RCH_2OH +    RCHO + Me_2S



-All Swern type complexes react with alcohols, in presence of base, to give "activated alcohol complexes".
-Examples:

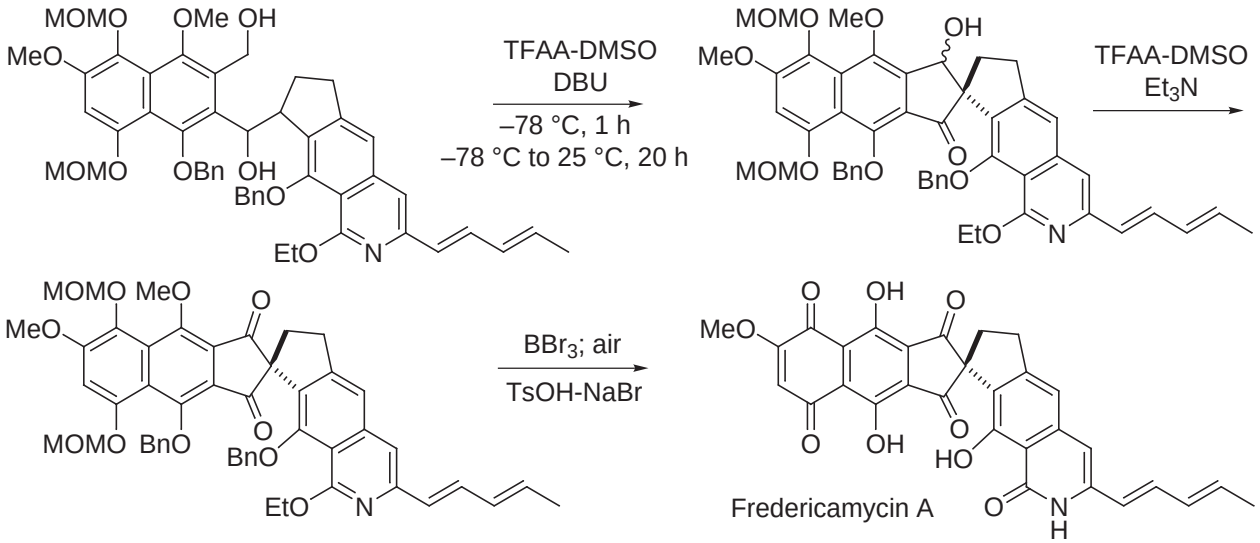
-Other oxidants cleave diol C-C bond
-Swern oxidation run under very mild conditions (usually –78 °C to –50 °C)





Boger *J. Org. Chem.* **1990**, *55*, 1519.
Boger *J. Org. Chem.* **1991**, *56*, 2115.
Boger *Tetrahedron Lett.* **1989**, *30*, 2037.

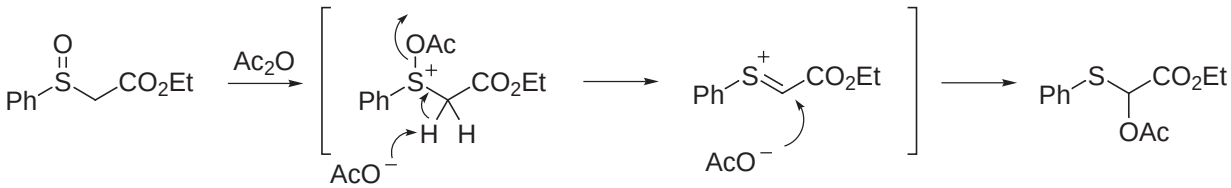
-Fredericamycin A: Boger *J. Am. Chem. Soc.* **1995**, *117*, 11839.



Note: **Kornblum oxidation**, *J. Am. Chem. Soc.* **1957**, *79*, 6562 via DMSO oxygen based displacement of halide (usually activated: benzylic or α-keto halide) to provide aldehyde or ketone.

- Common byproducts of Swern oxidations are (methylthio)methyl ethers and the amount varies with DMSO coactivator and reaction temperature. It is derived from alcohol trap of a Pummerer rearrangement intermediate: $CH_2{=}^{+}SCH_3$.

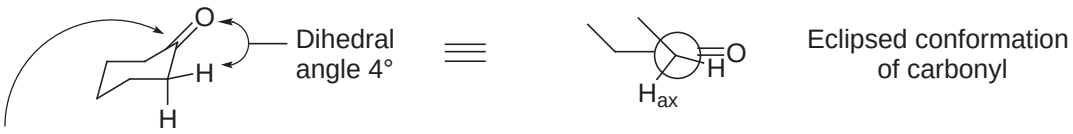
Note: **Pummerer rearrangement** is also a formal oxidation reaction
Pummerer *Chem Ber.* **1909**, *42*, 2282; *Chem Ber.* **1910**, *43*, 1401.



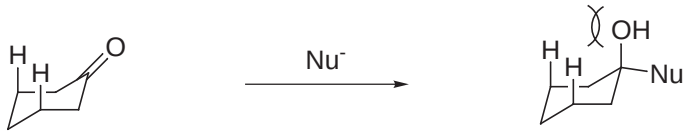
Reviews: *Org. React.* **1991**, *40*, 157. *Comprehensive Org. Syn.*, Vol. 7, pp 194-206.

VI. Reduction Reactions

A. Conformational Effects of Carbonyl Groups on Reactivity



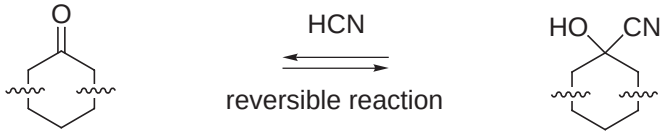
$sp^2 \leftarrow sp^3$
$120° \leftarrow 109.5°$
introduces
torsional strain → This torsional strain accounts for the increased reactivity of six-membered ring cyclic ketones over acyclic ketones.



Overall, the addition to cyclohexanones is favorable:
1. gain 1,3-diaxial interactions (A value = 0.7 kcal/mol for OH)
2. lose the torsional strain (~3-5 kcal/mol)

- So, additions to cyclic ketones are thermodynamically and kinetically favorable.

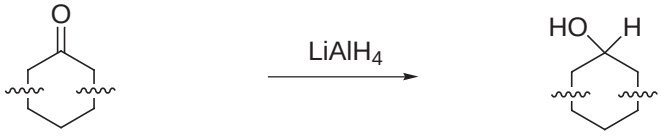
1. Reversible Reactions



$$K_{eq} \text{ for } \frac{\text{cyclohexanone}}{\text{acyclic ketone}} \simeq 70$$

- Thermodynamically more favorable for cyclohexanone due to the loss of torsional strain.
- Thermodynamic effect of sp^2 hybridization: the strain free acyclic system does not suffer the strain destabilization of the ground state, so little gain going from sp^2-> sp^3.

2. Irreversible Reactions (kinetic effect is pertinent)

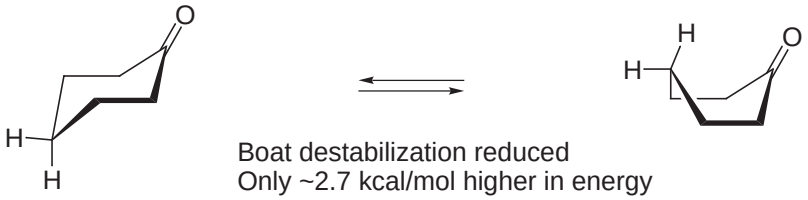


$$\text{Rate } (k) \text{ for } \frac{\text{cyclohexanone}}{\text{acyclic ketone}} \simeq 335$$

*Implication: One can selectively reduce a cyclic carbonyl in the presence of an acyclic carbonyl: under kinetic or thermodynamic conditions.

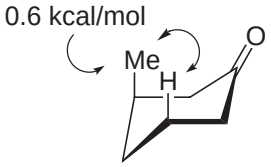
- Synthetic consideration: may not have to protect acyclic ketone.

3. Additional Conformational Effects



Boat destabilization reduced
Only ~2.7 kcal/mol higher in energy

-Cyclohexanones potentially have more accessible conformations available.



A = 1.8 kcal/mol
1/2 = 0.9 kcal/mol
Predicted!

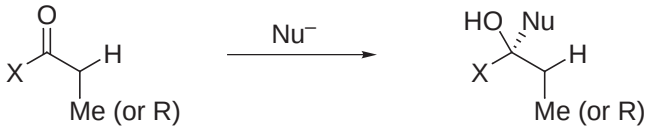
Theoretical prediction (0.9 kcal/mol), actually this 1,3-diaxial Me - H interaction is only about 0.6 kcal/mol. This difference (0.3 kcal/mol) in energies observed between theoretical and experimental results is due to the fact that the sp^2 carbonyl carbon moves these groups (Me and H) further away from each other: bond angle of 120° vs. 109.5°.

- Substituents on the ring benefit from a reduced A value since one axial substituent is removed and the opened bond angle of the carbonyl further reduces the remaining 1,3-diaxial interaction (greater distance).

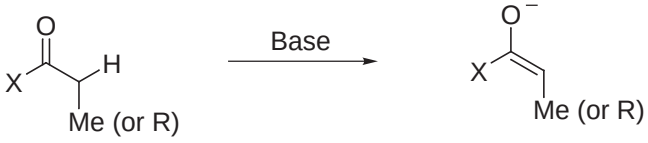
B. Reactions of Carbonyl Groups

- Three primary reactions which we will discuss relative to nucleophilic addition:

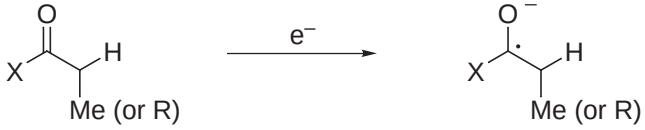
Nucleophilic addition:



α-Deprotonation:
(enolate formation)



Addition of e^-, formation of radical anion:

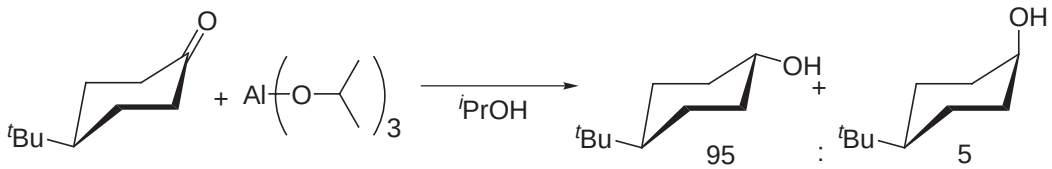


- Each reagent will display competitive reactions among the three primary pathways. Nature of each reagent and the nature of X will determine the course.

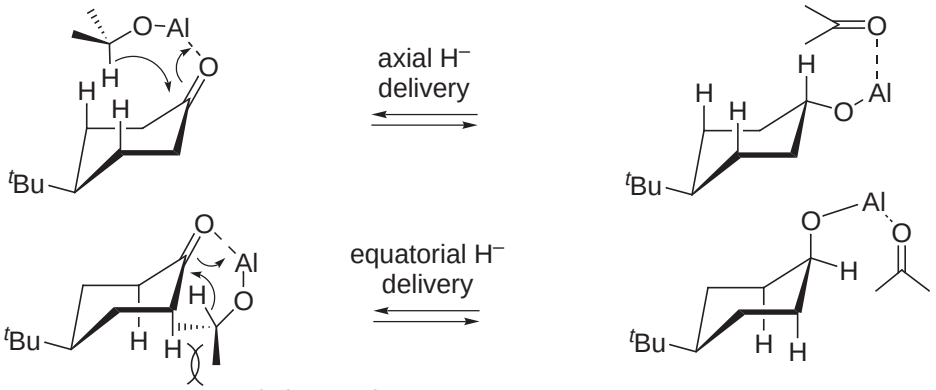
C. Reversible Reduction Reactions: Stereochemistry

- Meerwein-Pondorff-Verley Reduction (the reverse reaction is the Oppenauer Oxidation). ⟹ Reversible Reduction

Review: Djerassi *Org. React.* **1951**, *6*, 207.



- Mechanism: Reversible Intramolecular Hydride Transfer.



- Since it is freely reversible, one obtains the most stable alcohol from the reduction. The reaction is driven to completion by use of excess reagent and by distilling off the acetone formed in the reaction.

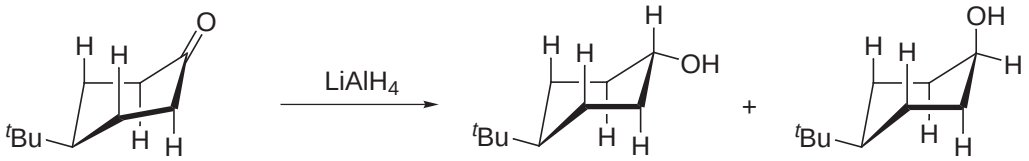
- But, the A value of OH = 0.7 kcal/mol and $K = e^{-\Delta G/RT}$ would predict a 72:28 ratio. Why does the experimental result give better selectivity than the prediction (95:5 > 72:28)?

- We must not only consider the A value, but the larger 1,2-destabilizing steric interactions of the isopropoxy group in the transition state for the equatorial delivery of the hydride: that is, the larger ΔE in the transition state.

D. Irreversible Reduction Reactions: Stereochemistry of Hydride Reduction Reactions and Other Nucleophilic Additions to Carbonyl Compounds

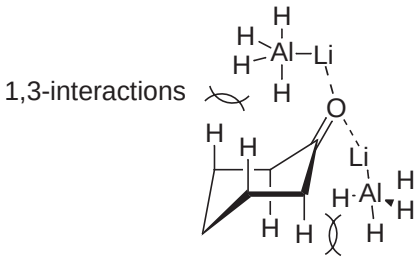
1. Cyclic Ketones

a. Examples



Nearly the same ratio obtained under these kinetic and the above thermodynamic conditions.

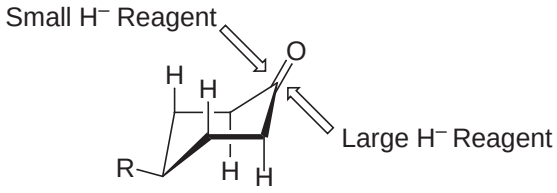
Why?



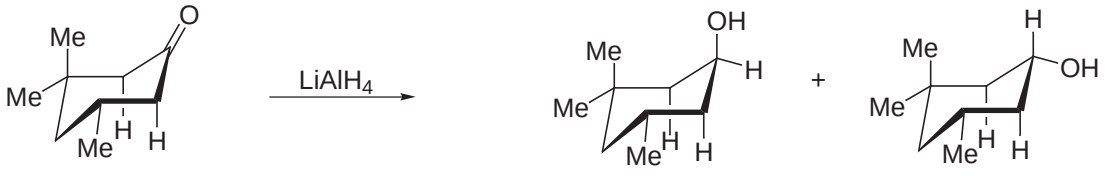
- Difference in the relative rates: 1,2-interactions slow the equatorial addition by a factor of ~ 10
- $LiAlH_4$ = small reagent ⟹ favor axial hydride delivery

- 1,3-interactions are more remote (i.e., smaller), when compared to the 1,2-interactions (larger).
- The destabilizing 1,3-interactions increase as the size of the reagent increases or with the size of the 1,3-diaxial substituents while the 1,2-interactions are not nearly so sensitive to the size of reagents or the size of the substituents.

- For the reduction of cyclohexanone and derivatives, we see the following generalizations:

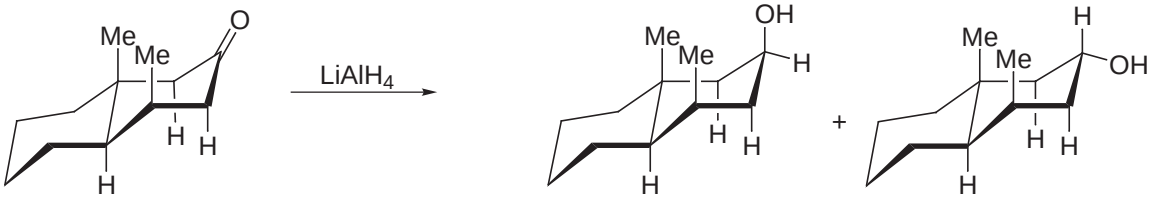


Examples:



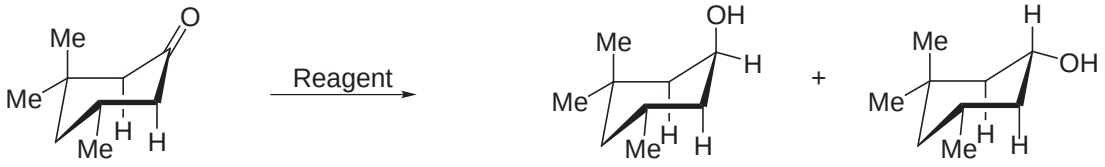
45 : 55

Increased steric hinderance of the 1,3-diaxial interactions (Me/reagent) make axial hydride delivery more difficult.



100 : 0

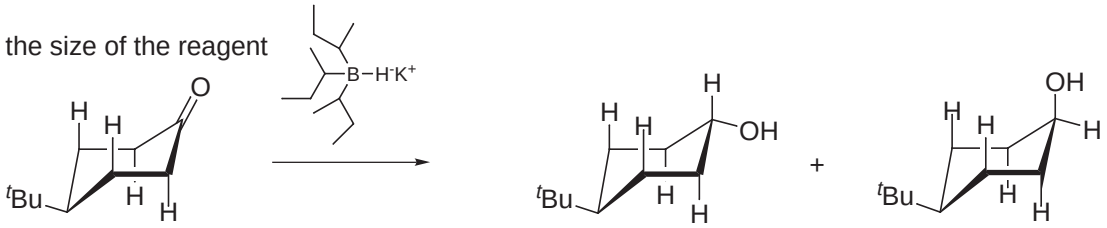
Serious 1,3-interactions preclude axial delivery of the hydride, but the axial Me's have no effect on the 1,2-interactions.



$LiAlH_4$	52 - 63	:	37 - 48
$NaBH_4$	55 - 64	:	36 - 45
$LiAl(OMe)_3H$	92 - 98	:	2 - 8

Larger reagent: greater selectivity for equatorial H^- delivery.

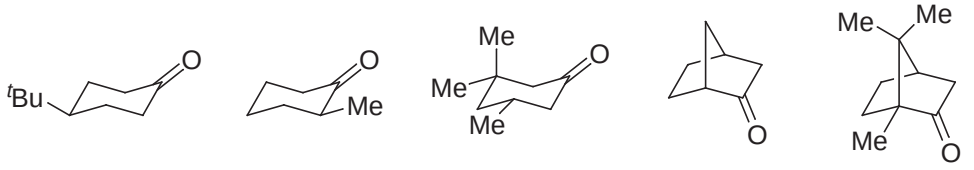
Effect of the size of the reagent



3.5 : 96.5

Much larger reagent! Now, even the 1,3-H/reagent interactions are large while the 1,2-torsional interactions are not affected. Brown *J. Am. Chem Soc.* **1972**, *94*, 7154.

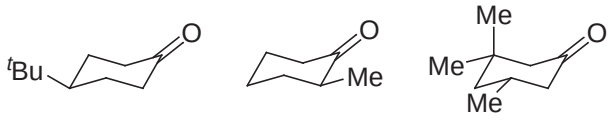
- Comparison of Diastereoselectivity of Hydride Reducing Reagents.



Reagent	% axial OH	% axial OH	% axial OH	% endo OH	% endo OH
$NaBH_4$	20	25	58	86	14
$LiAlH_4$	8	24	63	89	8
$LiAl(OMe)_3H$	9	69	92-98	98	1
$LiAl(O^tBu)_3H$	9	36	95	94	6
$(^sBu)_3BHLi$	93	98	99.8	99.6	0.4
$(Me_2CHCHMe)_3BHLi$	>99	>99	-	>99	no reaction
$LiMeBH_3$	2	13	66	-	-

Brown *J. Am. Chem. Soc.* **1970**, *92*, 709; **1972**, *94*, 7159; **1976**, *98*, 3383.

- Stereochemistry of Other Representative Nucleophilic Additions to Cyclohexanones.



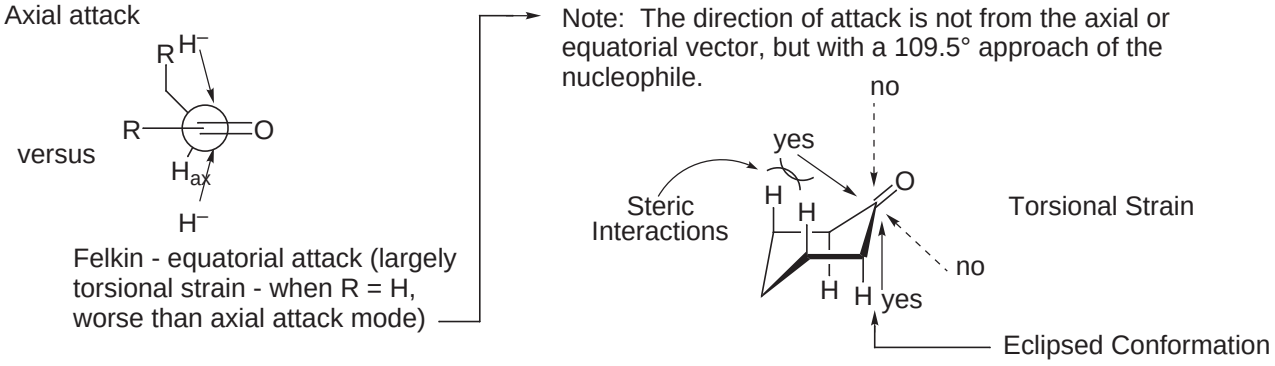
Reagent	% axial OH	% axial OH	% axial OH
$MeLi/Et_2O$	65	85	100
$MeMgI/Et_2O$	53	84	100
$EtMgBr/Et_2O$	71	95	100
$PhMgBr/Et_2O$	49	91	100
PhLi	58	88	-

Note: Typically alkyllithium reagents behave as large nucleophiles and approach from the equatorial direction

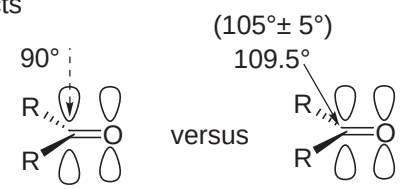
Ashby *Chem. Rev.* **1975**, *75*, 521.

V. Grignard received the 1912 Nobel prize in Chemistry for his discovery of the role of organomagnesium halides in organic synthesis which he made as a graduate student working with P. A. Barbier.

b. Origin of Diastereoselectivity

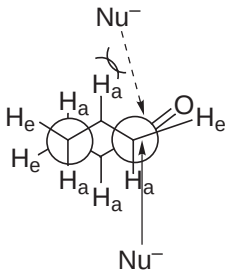


- Stereoelectronic effects



Dunitz angle: *Tetrahedron* **1974**, *30*, 1563. Good overlap and ~ approaches bond angle required of sp^3 hybridization. Better $\sigma - \pi^*$ overlap (FMO) for nucleophilic addition.

- Cyclic Ketones: Steric vs. Torsional Interactions.



- As the nucleophile gets larger, this steric interaction with the C_3 - axial H gets worse - equatorial approach becomes the preferred line of attack.

- For C_3 and C_5-H substituents, this torsional interaction is worse than the steric interaction of Nu^- / C_3 and C_5-H's (for small, unhindered Nu^-).

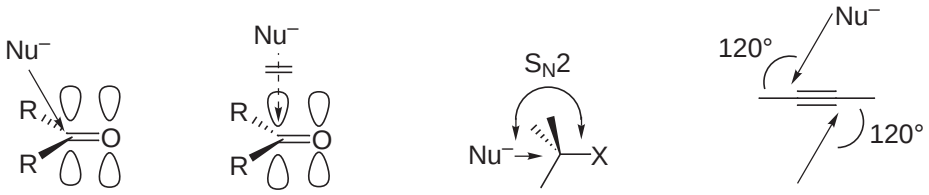
- All H^- reductions have transition states that resemble reactant geometry.
- Diastereoselectivity is influenced by:
  1) Steric interactions (1,3-diaxial interactions)
  2) Torsional strain (1,2-interactions)
  3) Remote electronic effects (electrostatic interactions)
- In contrast to early theories of "product development control" / late transition state vs "steric approach control" / early transition state.

c. Baldwin's Rules and Dunitz Angle of Attack

Recent review: *Acc. Chem. Res.* **1993**, *26*, 476.
Dunitz angle of attack: *Tetrahedron* **1974**, *30*, 1563.

- Nucleophile addition to carbonyl compound takes place not at 90° (perpendicular) to the C=O, but at an angle of ~105° ± 5°

sp^2 = 105° ± 5° sp^3 = 180° sp = 120°

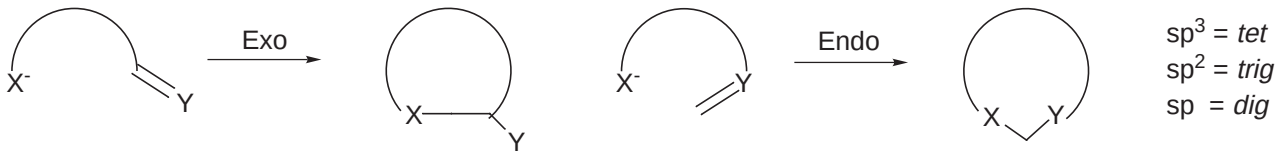


- First detailed by Eschenmoser *Helv. Chem. Acta* **1970**, *53*, 2059.

- Expanded and elaborated to: Baldwin's Rules for Ring Closure
J. Chem. Soc., Chem. Commun. **1974**, 734, 736.

- Vector analysis and approach trajectory on sp^2, sp, and sp^3 systems.

- For intramolecular reactions the favored pathways are those where the length and nature of the linking chain enables the terminal atoms to achieve proper geometry for reaction.

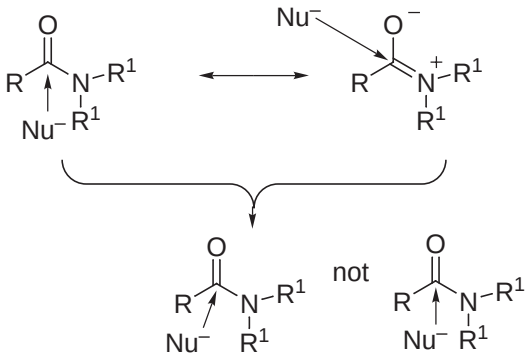


Baldwin's Rules

Rule 1: tetrahedral (sp^3) systems	**Rule 2**: trigonal (sp^2) systems	**Rule 3**: digonal (sp) systems
(a) 3 to 7-*exo-tet* are favored	(a) 3 to 7-*exo-trig* are favored	(a) 3 to 4-*exo-dig* are disfavored
(b) 5 to 6-*endo-tet* are disfavored	(b) 3 to 5-*endo-trig* are disfavored	(b) 5 to 7-*exo-dig* are favored
	(c) 6 to 7-*endo-trig* are favored	(c) 3 to 7-*endo-dig* are favored

-Baldwin: Approach Vector Analysis (Vector Sum establishes the approach of reagent).

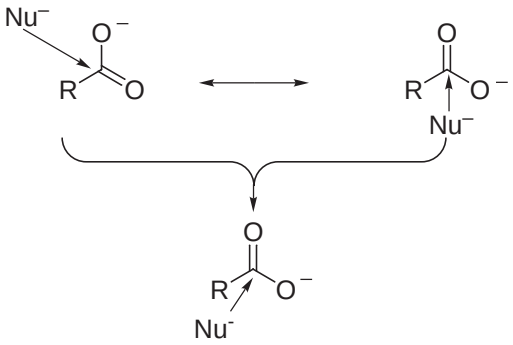
1. Amides



nonequivalent contributions of each resonance form

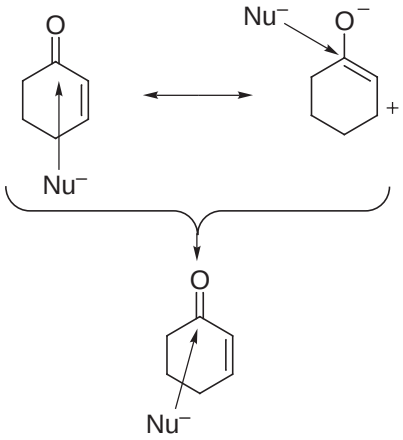
line of attack is weighted average of the two contributing resonance forms

2. Carboxylate



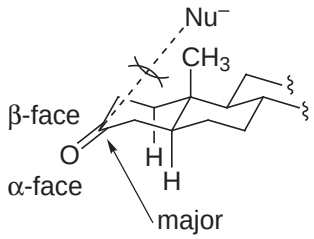
equivalent and Nu^- approaches over (eclipsing) the R group

3. Cyclohexenones

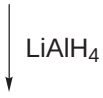


substituents in the C_5 and C_6 position will have a more significant effect on the rate and the stereochemical outcome

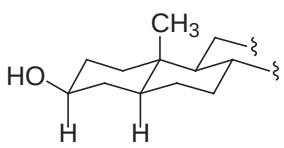
Examples:



- locked *trans* diaxial ring fusion
- preferential axial delivery of reagent
- equatorial OH is major product
- addition of Nu^- from β-face (equatorial delivery) suffers from repulsive interaction with axial Me

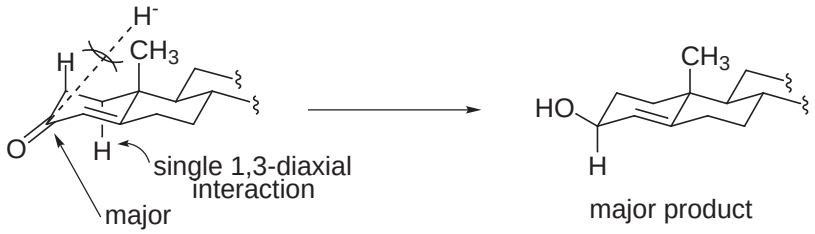


Houk and Trost *J. Org. Chem.* **1991**, *56*, 3656.

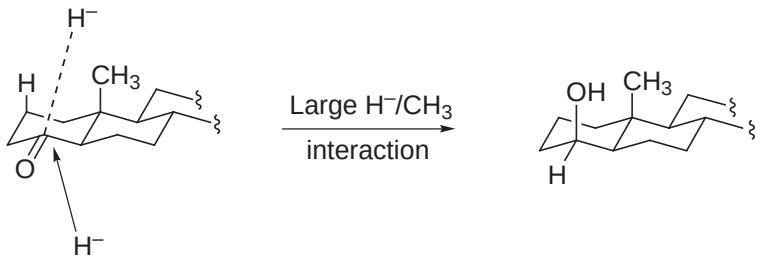


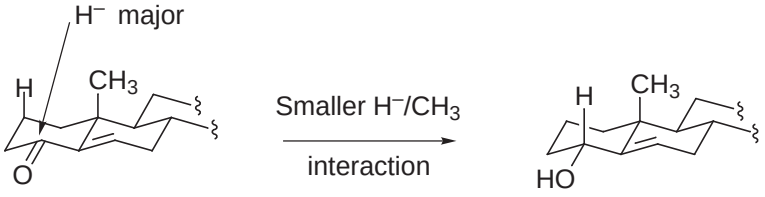
70~90%

- vs.



- but





- With enones, the substituents in the 5,6-positions play a more dominant role in determining stereochemical outcome of nucleophilic addition to the carbonyl.

2. Acyclic Carbonyl Groups

Review: *Comprehensive Org. Syn.*, Vol. 1, pp 49-75.

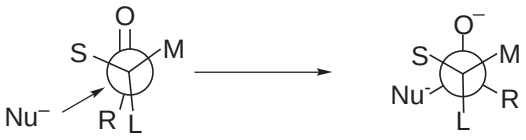
D. J. Cram was awarded the 1987 Nobel prize in Chemistry for his "host - guest" complex studies.

- Cram's Rule — *J. Am. Chem Soc.* **1952**, *74*, 5828. Empirical and no mechanistic interpretation is imposed on model *J. Am. Chem Soc.* **1959**, *81*, 2748. (chelation-controlled addition)
- Prelog — *Helv. Chim. Acta* **1953**, *36*, 308. (1,3-induction)
- Felkin model: (or Felkin-Ahn) — *Tetrahedron Lett.* **1968**, 2199, 2205. *Tetrahedron Lett.* **1976**, 155, 159. *Nouv. J. Chim.* **1977**, *1*, 61.

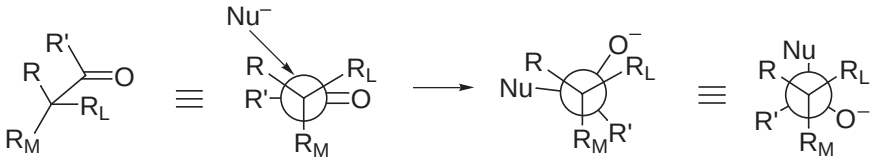
V. Prelog received the 1975 Nobel prize in Chemistry for his research into stereochemistry of organic molecules and reactions.

a. Cram's Rule

- Empirical Model



- Large group L eclipsed with R and not the carbonyl, Nu^- approach from side of small (S) group.
- Stereoselectivity observed usually modest.
- But, most populated (most stable) conformation of acyclic ketone would be the eclipsed carbonyl conformation.

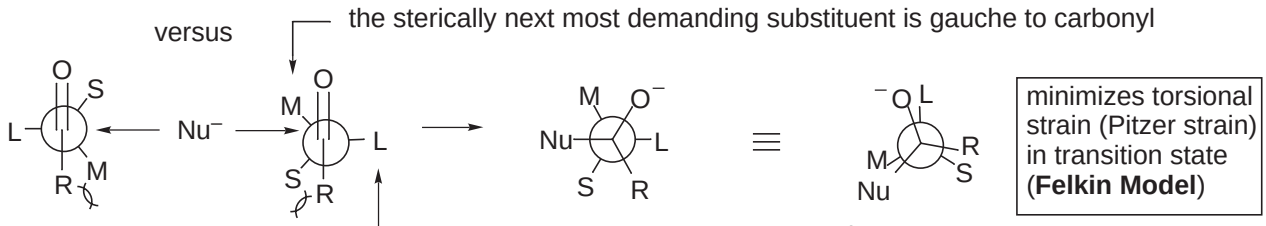


This is not the observed stereochemistry!

Note: Reaction is not from the ground state carbonyl eclipsed R_L conformation, i.e., the ground state conformation is not the reactive conformation (Curtin-Hammett Principle).

b. Felkin (-Ahn) Model

- Large group (L) *trans* antiperiplanar to forming bond

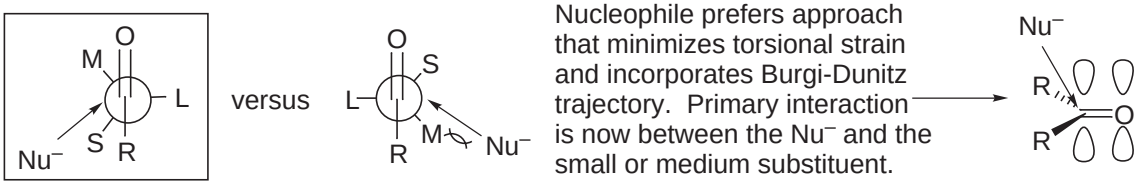


Same as Cram Product:

sterically most demanding group is perpendicular to the plane of the carbonyl, anti to incoming nucleophile

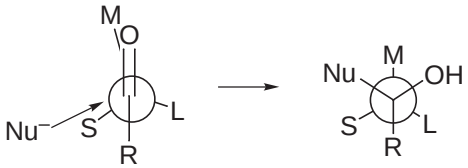
- Here, L is either the largest group (sterically) or the group whose bond to the α-carbon provides the greatest σ-π* overlap (e.g. halide, alkoxy groups).
- Computational studies of Ahn confirmed this is the most stable transition state and extended it to α-chloroketones. In the latter case, this minimizes destabilizing electrostatic interactions between the halogen (electronegative group) and the incoming nucleophile.

Ahn further refined the Felkin Model, i.e.,
Felkin-Ahn Model, as shown below



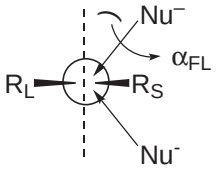
Preferred

Note: Karabatose proposed a similar model as an alternative to the original Cram empirical rationalization based on computational studies that suggested the most favored conformation would have the medium-sized group eclipsing the carbonyl and addition of H^- occurs from the side of the small substituent.



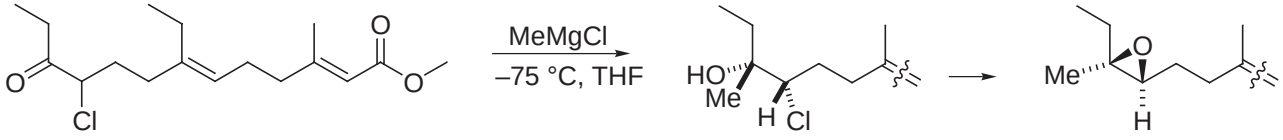
Karabatose *J. Am. Chem. Soc.* **1967**, *89*, 1367.

The model incorporating the Burgi-Dunitz angle has been even further refined to reflect the impact of substantially different sized R groups on the carbonyl. As the size difference between the two substituents increases, the incoming nucleophile would try to avoid the larger one and the approach vector would be tilted away from the normal plane by an angle referred to as the Flippin-Lodge angle (α_{FL}).

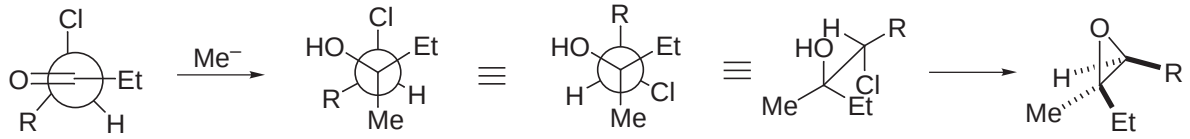


Heathcock *Aldrichchim. Acta* **1990**, *23*, 99.

Examples:



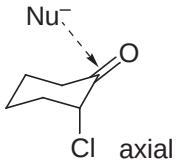
Johnson *J. Am. Chem. Soc.* **1968**, *90*, 6225.



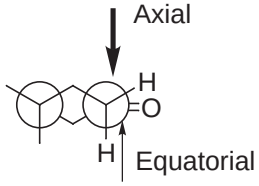
-First observed in cyclic systems: Cornforth

J. Chem. Soc. **1959**, 112 and 2539.
J. Chem. Soc. **1957**, 158.

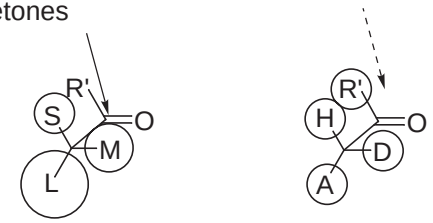
J. W. Cornforth received the 1975 Nobel prize in Chemistry jointly with V. Prelog for outstanding intellectual achievement on the stereochemistry of reactions catalyzed by enzymes.



-For cyclic ketones

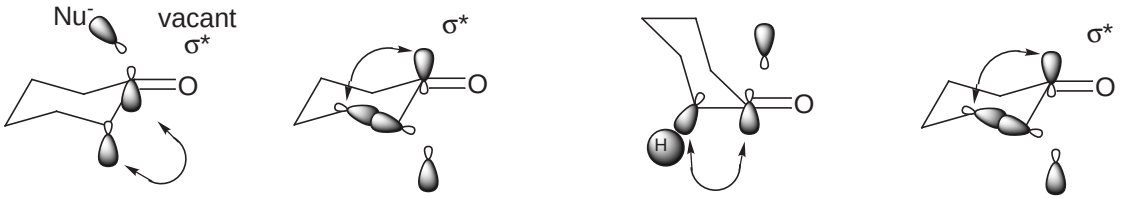


-For acyclic ketones



Allylic bonds prefer to be staggered (axial attack) with respect to the incoming nucleophile rather than eclipsing (equatorial attack).

c. Cieplak Model *J. Am. Chem. Soc.* **1981**, *103*, 4540.



1. C-H bond is more electron-rich, better σ e-donation in stabilization of the developing σ* of bond formation than C-C bond, therefore axial approach preferred.

2. σ C-O > σ C-H > σ C-C > σ C-S.

3. Nucleophile can affect intensity of effect, σ* (LUMO of developing bond).

   ↑ LUMO, ↓ effect, ↓ overlap/stabilization

   (a) Electron donation of solvent (polarity) will increase σ*, ↑ LUMO, ↓ overlap, ↑ equatorial attack, i.e. preferentially ↓ axial attack

   (b) Counterion effect: its ability to complex/stabilize σ*, lower σ* ↑ effect, ↑ axial attack.

   (c) Electron-rich Nu^-: ↑ σ* nucleophile, ↓ overlap/effect, ↓ axial attack ↑ equatorial attack.

4. Heteroatom at 4-position exhibits preference for axial attack: n - σ* stabilization.

d. Additional Models

- Product development/steric approach control

Dauben: *J. Am. Chem. Soc.* **1956**, *78*, 2579.

- Torsional strain (preference for staggered conformation in the transition state)

Felkin: *Tetrahedron Lett.* **1968**, 2199, 2205.

Houk: *J. Am. Chem. Soc.* **1987**, *109*, 908.
J. Am. Chem. Soc. **1988**, *110*, 3228.
Science **1986**, *231*, 1108.

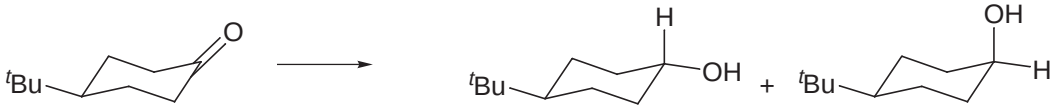
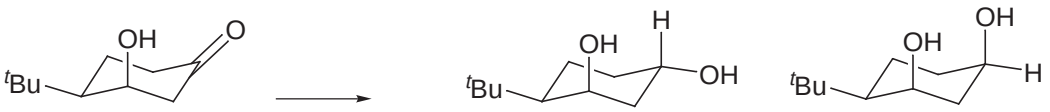
  Evans, Carreira, Chapman *J. Am. Chem. Soc.* **1988**, *110*, 3560.



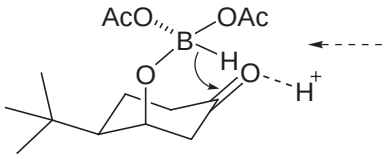
$NaBH_4$	90	:	10
$Me_4NBH(OAc)_3$	no reaction		



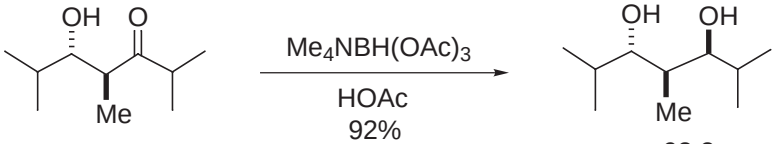
$NaBH_4$	1	:	1
$Me_4NBH(OAc)_3$	300	:	1

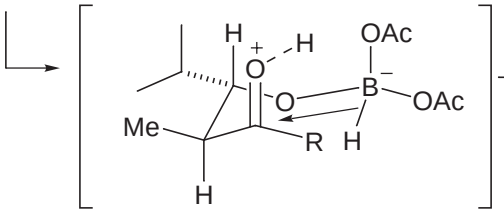
HOAc, low temperature protonates carbonyl,
activation for reduction, no reduction without HOAc

- Note that $Me_4NBH(OAc)_3$ is unreactive toward carbonyl unless carbonyl oxygen is protonated.
- The key to success is the lack of reactivity of the reagent in the intermolecular reaction, which permits formation of complex:

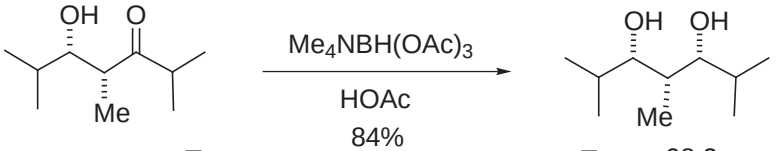


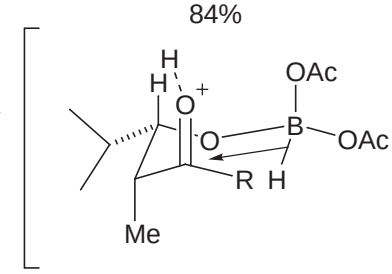
internal axial hydride delivery





has two equatorial substituents,
on the chair-like transition state
excellent diastereoselectivity



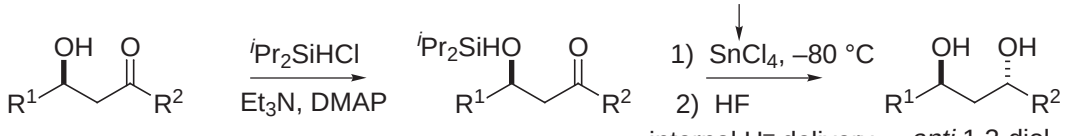


axial alkyl group, but no
destabilizing 1,3-diaxial
interactions

still observe excellent
diastereoselectivity

-Also, works with 
\+ Lewis acid (to activate carbonyl)

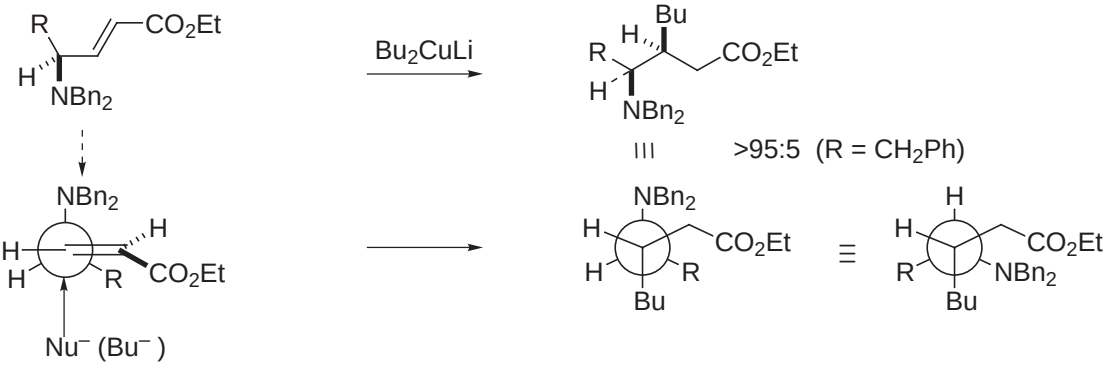
Lewis acid activation



Davis *Tetrahedron* **1988**, *44*, 3761.

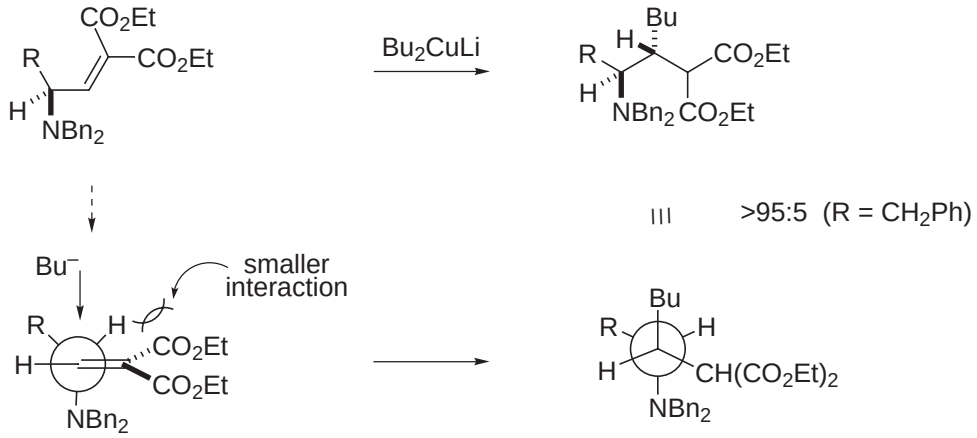
g. Felkin Addition to Other π-Systems

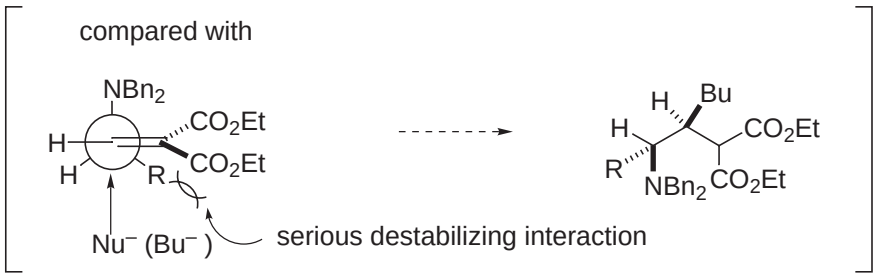
- Reetz *Angew. Chem., Int. Ed. Eng.* **1989**, *28*, 1706.



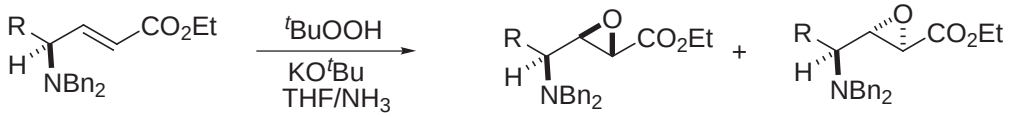
- Felkin Model

But,





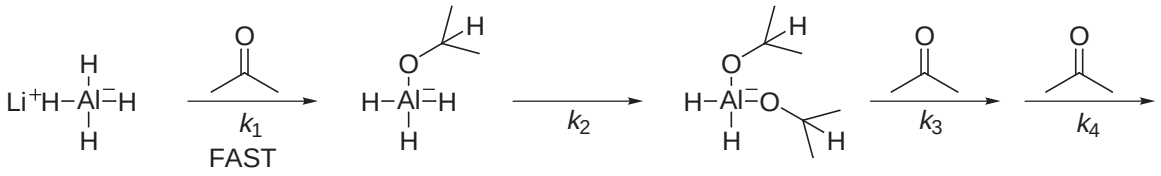
- Rationalize the following results:



R = CH_3	46%	> 96	:	4
R = $PhCH_2$	60%			
R = 	68%			
R = TBDMSOCH$_2$	80%			

E. Aluminum Hydride Reducing Agents

- $LiAlH_4$ coordinates with carbonyl oxygen and activates it towards reduction.



- Rate of addition decreases as additional alkoxy groups are placed on Al: $k_1 > k_2 > k_3 > k_4$, especially for hindered ketones.
- The aluminum alkoxide hydrides are stable in that they do not disproportionate.

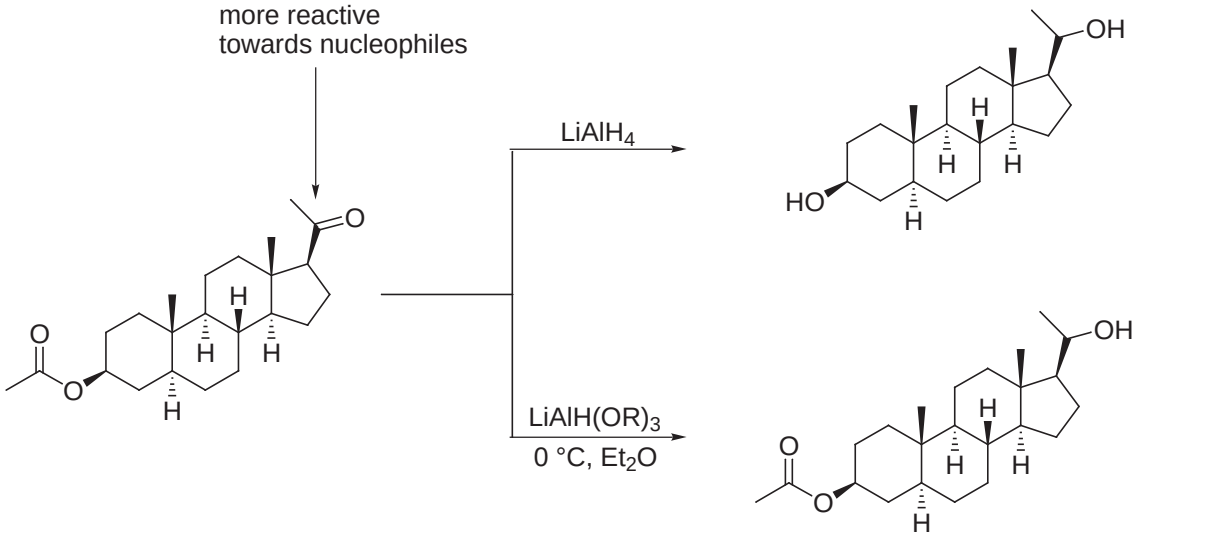
- Reagents have been designed which are less reactive, thus more selective:

  - Reactivity: $LiAlH_4 > LiAl(OR)H_3 > LiAl(OR)_2H_2 > LiAl(OR)_3H$

$$LiAlH_4 \xrightarrow{3\ ROH} LiAlH(OR)_3$$

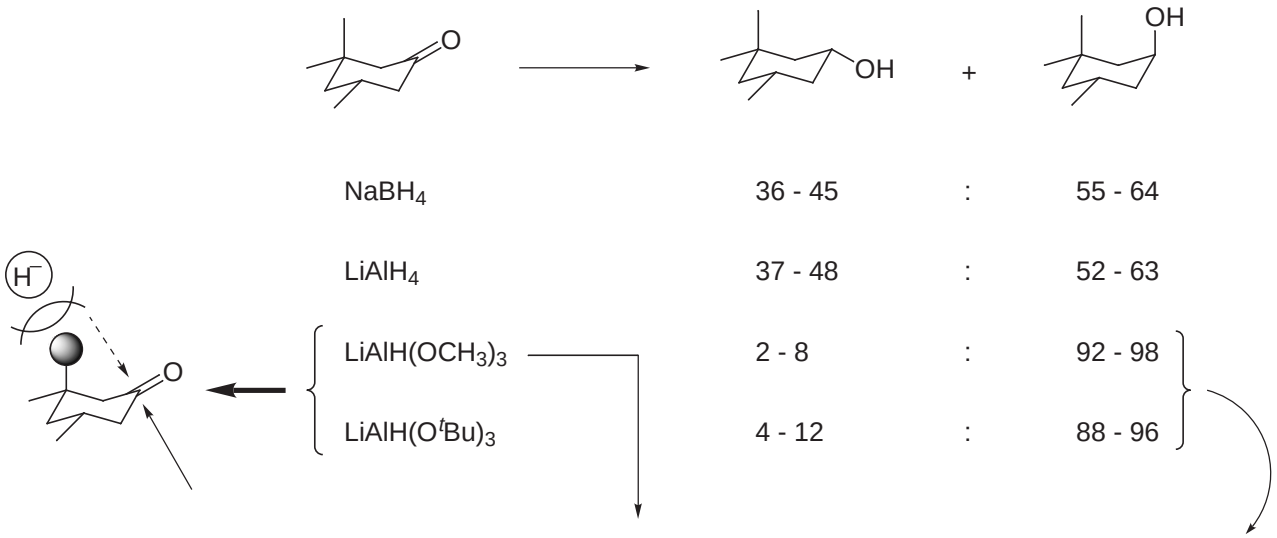
  - Most common are $LiAlH(OCH_3)_3$ and $LiAlH(O^tBu)_3$

- Examples:



Chemoselectivity: differentiation between competitive functional groups
vs.
Regioselectivity: differentiate between orientations.

- Lithium trialkoxyaluminumhydrides can be chemoselective.



- this is actually dimeric in solution, so effective bulk greater than $LiAlH(O^tBu)_3$

- degree of stereocontrol is concentration dependent with $LiAlH(OCH_3)_3$ (dimer and higher aggregates) but not $LiAlH(O^tBu)_3$ (monomeric)

F. Borohydride Reducing Agents

- Borohydrides (Na^+, Li^+, K^+, Zn^{2+}) are nucleophilic H^- sources.

- Alkoxyborohydrides $(RO)_3B^-H$ tend to disproportionate.

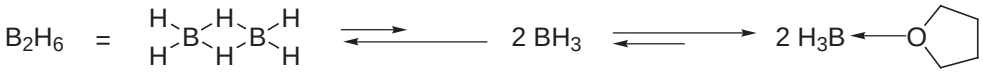
$$Na\ (RO)_3BH \rightleftharpoons NaBH_4$$

- Therefore, $k_1 \sim k_2 \sim k_3 \sim k_4$ for the stepwise reactions and you can't typically moderate the reactivity (electronically) by introducing alkoxy substituents.

- However, substitution with bulky alkyl groups on boron will moderate reactivity and diastereoselectivity.

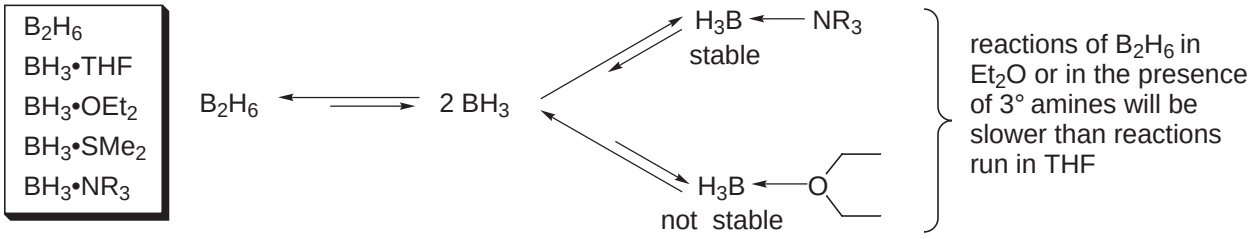
	$LiAlH_4$	75	:	25
	BH_3•THF	74	:	26
		21	:	79
Li-Selectride		<1	:	>99
K-Selectride		<1	:	>99

- NOTE: on diborane

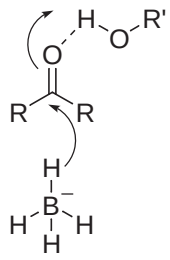


- THF optimally provides uncomplexed, monomeric BH_3 available for reduction (or other reactions).

- In ether (B_2H_6), or in the presence of amines (BH_3•NR_3), less reactive borane-complexes are formed.



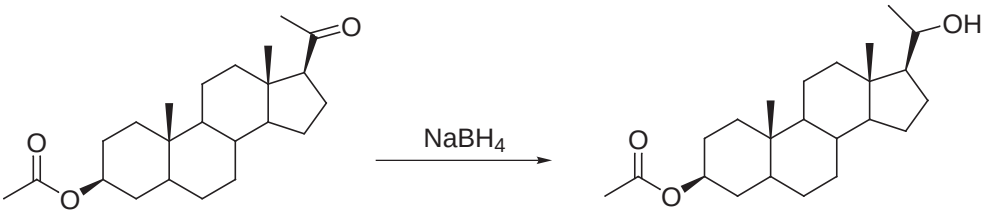
- $NaBH_4$ requires activation of the carbonyl by hydrogen-bonding with alcoholic solvent for reductions. Therefore the reactions are run in alcoholic solvents. The reagent slowly reacts with solvent: MeOH (30 min) > EtOH (slow) > ^{i}PrOH (stable) > ^{t}BuOH (stable).



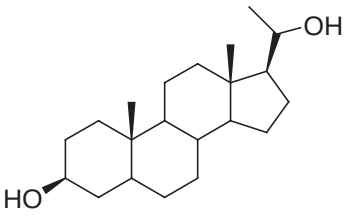
- But trialkylborohydrides ($R_3B^-HM^+$) are reactive enough to use in ethereal solvents (e.g., THF) and don't require this activation of C=O by solvent.

- $LiBH_4$ is also more reactive than $NaBH_4$ (Li^+ coordinates better to carbonyl oxygen, activating the carbonyl toward attack by H^-).

- Differences in reactivity can give rise to Chemoselectivity:



$LiBH_4$



House, pp 71-105 (discussion of reducing agent choice)

H. Characteristics of Hydride Reducing Agents

Borohydrides

1. $NaBH_4$

- Review: *Aldrichim. Acta* **1979**, *12*, 3.

- Mild reducing agent used primarily for the reduction of aldehydes and ketones.

- Also available as $NaBD_4$, $NaBT_4$ (although somewhat less reactive) for labelling.

- H^+ workup of $NaBH_4$ reductions may form BH_3 (if excess $NaBH_4$ used)
  ⇢ might react with other functional groups (this is the origin of the discovery of BH_3 and its hydroboration of alkenes).

- $NaBH_4$ reacts with H_2O, CH_3OH at 25 °C ⟶ ca. 30 min
  reacts only slowly with EtOH (good solvent), is stable in ^{i}PrOH or ^{t}BuOH and can also be used in diglyme but the reduction is very slow.

2. $NaCNBH_3$

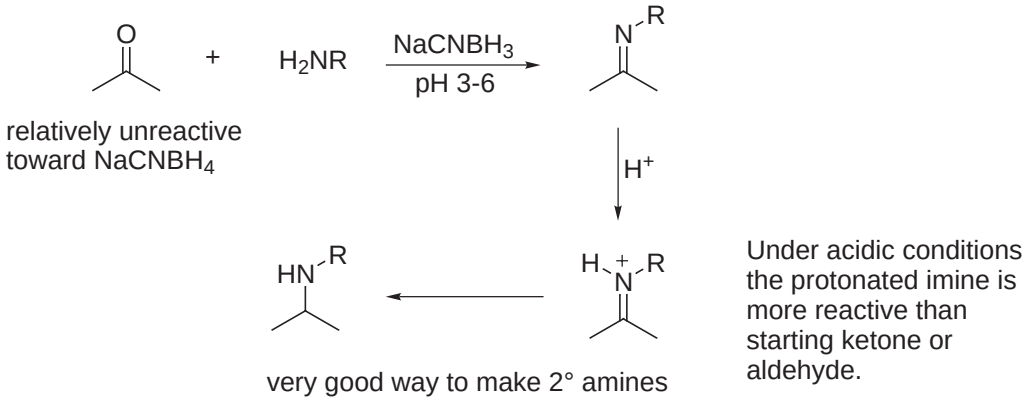
- Less reactive than $NaBH_4$.

- Stable in aqueous solutions - at pH > 3 (permits activation of C=O by protonation).

- Can be used in CH_3OH.

- Can be used in THF but reduction very slow.

- Reductive amination:



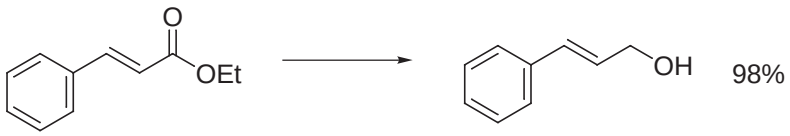
- Review: *Comprehensive Org. Syn.*, Vol. 8, pp 25-78. This review also discusses the diastereoselectivity of cyclic/acyclic imine/iminium reductions with comparisons to the corresponding ketone. Many similarities but also many important distinctions.

3. $LiBH_4$

- More reactive than $NaBH_4$ (Li^+ activates C=O by coordination).

- Can be used in THF, diglyme and non protic solvents.

- Excellent reagent for mild reductions.



- clean 1,2-reduction!

- $NaBH_4$ does not typically reduce esters

4. Me_4NBH_4, Et_4NBH_4

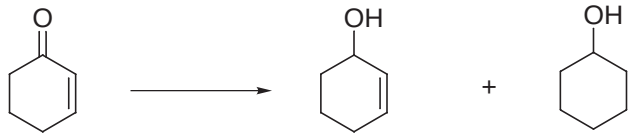
- Soluble in nonpolar aprotic solvents (e.g., THF, benzene).

5. $Zn(BH_4)_2$

- Good in instances of potential competing 1,4-reduction.

- Zn^{+2} coordinates to and activates carbonyl.

- Good for chelation-controlled reductions.



$Zn(BH_4)_2$	96%	4%
$NaBH_4$	59%	41%

- Review: Narasimhan *Aldrichim. Acta* **1998**, *31*, 19.

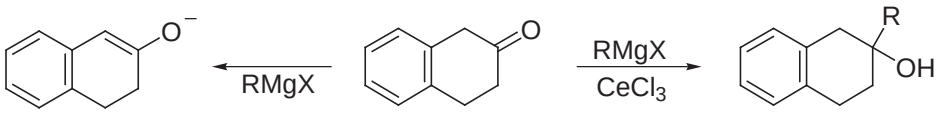
6. $NaBH_4/CeCl_3$ (catalytic amount (0.1 equiv))

- Luche *J. Am. Chem. Soc.* **1981**, *103*, 5454; **1978**, *100*, 2226.

- Readily enolizable carbonyl can be reduced.

  - also true of other nucleophiles

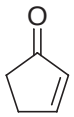
  - clean addition, no enolization

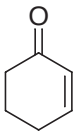


Imamoto *J. Am. Chem. Soc.* **1989**, *111*, 4392.

- No conjugate reduction: clean 1,2-reduction.

-Reagent comparisions for 1,2- vs. 1,4-reduction





Reagent	1,2 : 1,4		1,2 : 1,4		
$LiAlH_4$	85 : 15	(100%)	94 : 6	(97%)	
$NaBH_4$	0 : 100	(100%)	59 : 41	(90%)

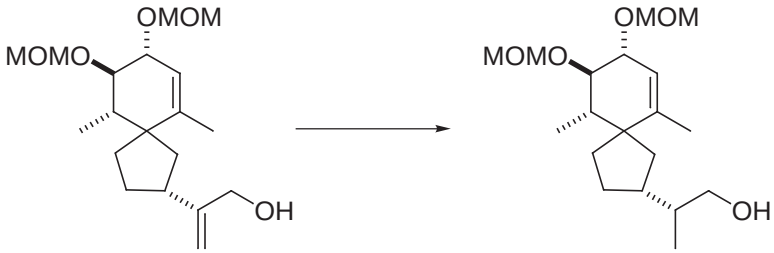
DIBAL-H	98 : 2	(81%)	98 : 2	(100%)	← Masamune *J. Chem. Soc., Chem Commun.* **1970**, 213.
DIBAL-H/^{n}BuLi	99 : 1	(83%)	94 : 6	(96%)	
9-BBN	>99 : 1	(85%)	>99 : 1	(85%)	← Brown *J. Org Chem.* **1977**, *42*, 1197.
$LiAlH(OMe)_3$	90 : 10		95 : 5		
$LiAlH(O^tBu)_3$	0 : 100		22 : 78		

7. $NaBH_4$-$CoCl_2$

- Selective reduction of nitriles.

Ganem *J. Am. Chem. Soc.* **1982**, *104*, 6801

- But will also reduce olefins, allylic alcohols, and ketones.



Swato *Chem. Pharm. Bull.* **1990**, *33*, 361.

8. $Me_4NBH(OAc)_3$ and $NaBH(OAc)_3$

- Unreactive, no intermolecular ketone reductions.

- OAc can exchange with substrate alcohol and provides opportunity for intramolecular reductions (CH_3CN-HOAc). Used to form *anti*-1,3-diols from acyclic β-hydroxyketones.

9. $KBH(O^iPr)_3$

- Stable (does not undergo disproportionation reaction as with other alkoxy BH), mild reagent.

- Used in THF and only reduces aldehydes and ketones; bulky reagent so it gives equatorial attack on cyclohexanones.

10. 9-BBN 
- Stable solid; more stable and less reactive/more selective.

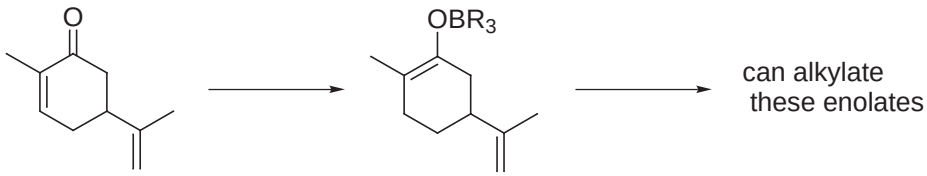
- Gives good 1,2- vs. 1,4-reduction selectivity.

- Very selective reagent.

11. Li-Selectride  **K-Selectride** 
- Large reagents, near exclusive cyclohexanone equatorial H^-delivery.

- Very bulky.

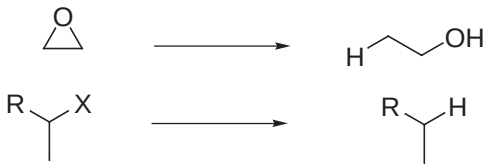
- Very reactive and give preferential 1,4-reduction.



Ganem *J. Org. Chem.* **1976**, *41*, 2194.

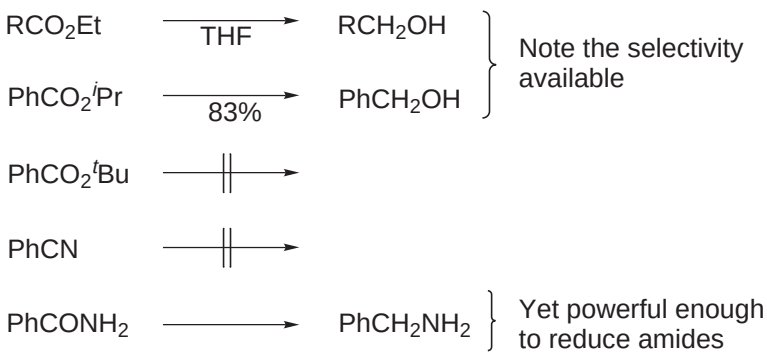
12. $LiBHEt_3$ (Super Hydride)

- Very powerful (stronger than $LiAlH_4$), so good for reductions which are otherwise slow.



13. $NaBH_4$-$HSCH_2CH_2SH$ 
- Used in THF.

- Guida *J. Org. Chem.* **1984**, *49*, 3024.



Aluminum Hydrides

14. $LiAlH_4$

- $LiAlD_4$ and $LiAlT_4$ are also available for labelling.

- Reductions can be conducted in ether, THF, DME, diglyme.

- Workup best conducted by 1,2,3 method:

  for 1.0 g $LiAlH_4$ used, add 1 mL H_2O (slowly)
  then 2 mL of 10% aqeous NaOH, then 3 mL
  H_2O ⟶ Al salts are now easily filtered

15. $NaAlH_4$

- Not quite as reactive as $LiAlH_4$, but still quite strong reducing agent.

- THF, DME, diglyme solvents.

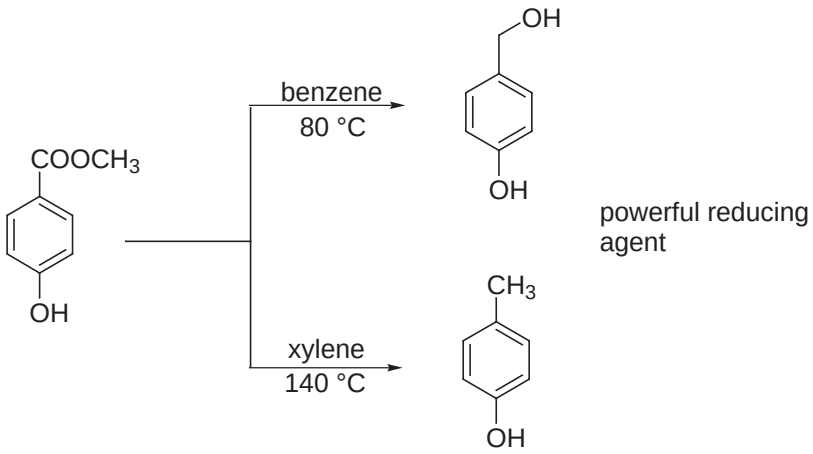
16. $LiAlH(O^tBu)_3$ / $LiAlH(OEt)_3$ / $LiAlH(OMe)_3$

$LiAlH(OMe)_3$ ⟶ this is the largest reagent (due to aggregation) of the three

- Use in THF, diglyme.

- Review on alkoxyaluminum hydrides: *Org. React.* **1985**, *34*, 1; **1988**, *36*, 249.

17. $NaAlH_2(OCH_2CH_2OMe)_2$ = REDAL-H



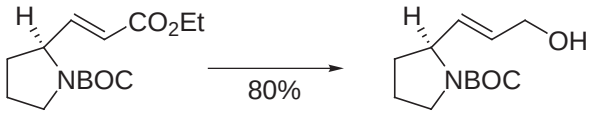
- Xylene, benzene, toluene good solvents.

- Good for epoxide openings (especially if able to be directed by proximal OH), halide and sulfonate reduction.

18.  **= DIBAL-H**

- Good for RC≡N ⟶ RCHO via 
- Because there is no metal cation (Li^+, K^+, etc.) in the reagent, very good for directed reductions (i.e., chelation-controlled reductions).

- Good for 1,2- vs. 1,4-reduction.



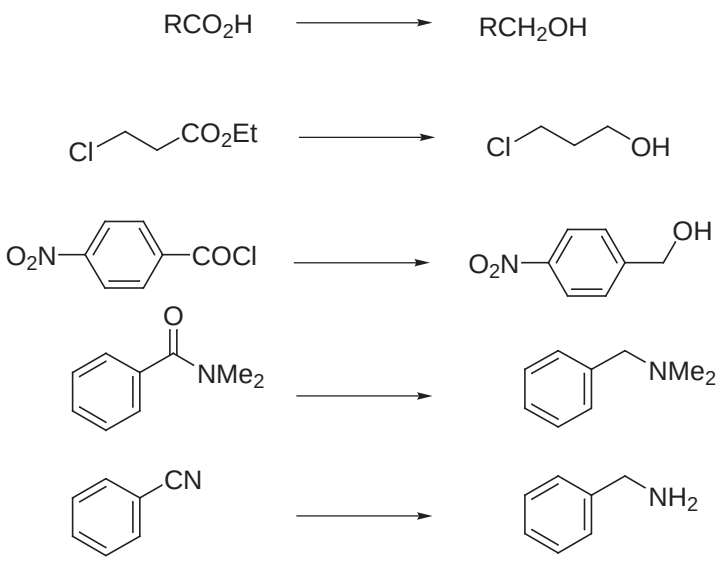
- Also good for RCOOR' ⟶ RCHO

via 
stable at –78 °C but breaks down at higher temperatures to give alcohol (upon further reduction) ⟶ to get RCHO, quench must be conducted at –78 °C (use MeOH or HOAc as proton source, H_2O freezes into a solid) then warm to 25 °C

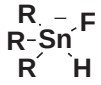
- Also, use of noncoordinating hydrocarbon solvent (toluene) provides better control than THF for reductions to RCHO.

19. AlH_3
AlH_3-NR_3

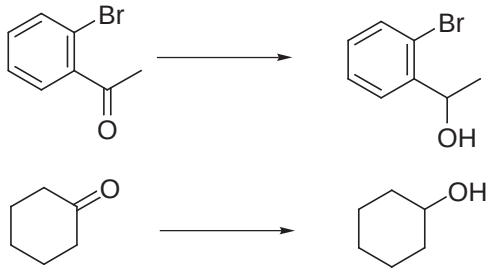
- Park *J. Org. Chem.* **1990**, *55*, 2968.



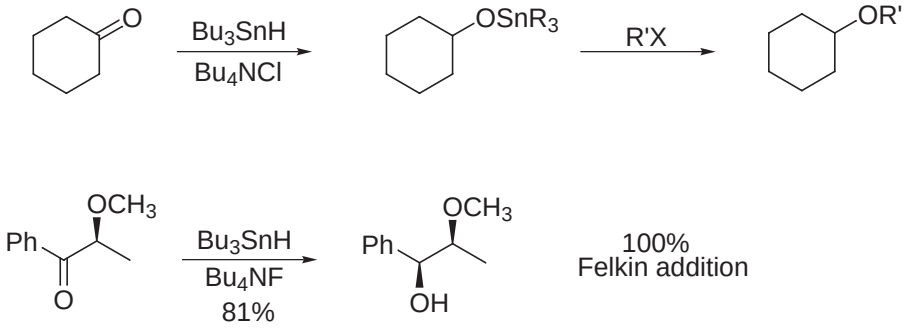
20. Bu_3SnH-Bu_4NX, X = Cl, F



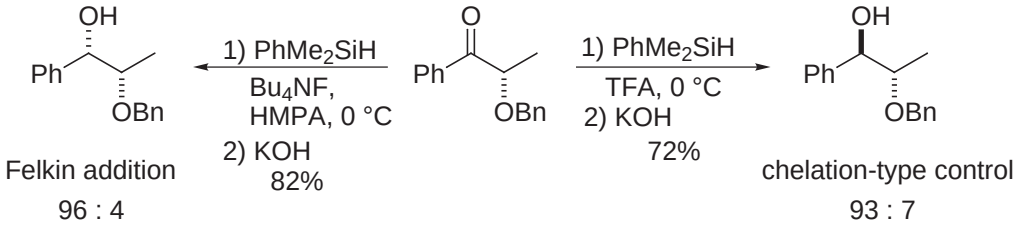
- Shibata *Chem. Lett.* **1991**, 307.



- Can alkylate intermediate directly:



21. $PhMe_2SiH$



Felkin addition
96 : 4

chelation-type control
93 : 7

Fujita *J. Org. Chem.* **1988**, *53*, 5405 and 5415.

22. $(EtO)_3SiH$/catalytic $Ti(O^iPr)_4$

- No solvent, stable to air.

- Reduces esters to alcohols in the presence of a wide variety of functional groups.

- Buchwald *J. Org. Chem.* **1992**, *57*, 3751.

P. Sabatier received the 1912 Nobel Prize in Chemistry for his contributions to catalysis, especially the hydrogenations of unsaturated organic compounds.

- *Comprehensive Org. Syn.,* Vol. 8, pp. 417 and 533.
- *Comprehensive Org. Syn.,* Vol. 8, pp. 471.

1. H_2 delivery from least hindered face of double bond.

2. Cis - H_2 delivery

   - activity of catalysts toward C=C: Pd > Rh > Pt > Ni > Ru

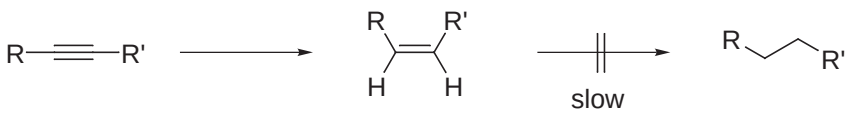
3. Increasing substitution on olefin decreases reactivity.

   - note potential isomerization of olefin and H-migration/allylic exchange in D_2/T_2 hydrogenations

4. Alkynes are more reactive than alkenes. Reagents have been developed to selectively prepare olefins from alkynes without over reduction:

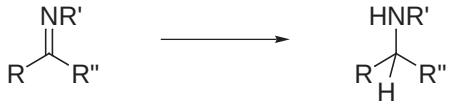
   - Lindlar catalyst: $Pd(BaSO_4)$

      - only reduce alkyne to alkene (*cis*)



5. Many kinds of catalyst, but most common are 5% ~ 10% Pd/C or PtO_2

- PtO_2 is particularly good for imine reduction to amines.



- Amines will poison Pd/C catalyst, but not Pt(0).

- Raney-Ni (Ra-Ni) also useful (especially for removing sulfide groups).

- $(Ph_3P)_3RhCl$ Wilkinson's catalyst (homogeneous).

  - a homogeneous catalyst (e.g., dissolve in organic solvent for reaction).

  - Review: *Org. React.* **1976**, *24*, 1.

- One of the earliest, successful examples of catalytic asymmetric synthesis entailed the homogeneous hydrogenation of enamides to provide amino acid derivatives

G. Wilkinson received the Nobel Prize in Chemistry in 1973 for deducing the structure of metallocenes.

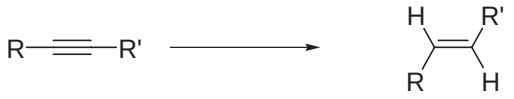
K. Dissolving Metal Reductions

1. Birch Reduction

- Reviews: *Comprehensive Org. Syn.*, Vol. 8, 489.
Org. React. **1992**, *42*, 1 (aromatic ring reduction).
Org. React. **1984**, *23,* 1 (carbonyl and enone reductions).



trans alkene
- most stable product

- First reported by Wooster *J. Am. Chem. Soc.* **1937**, *59*, 596.

- Extensively developed by Birch *Quart. Rev., Chem. Soc.* **1950**, *4*, 69.

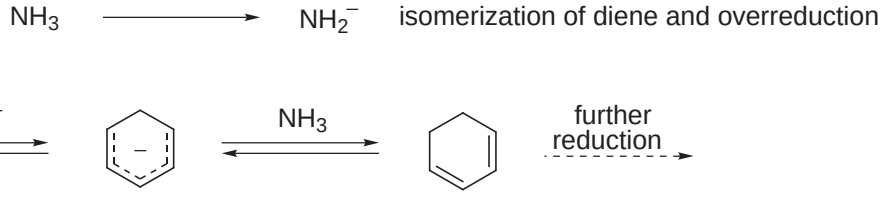
b. Solvent system

- Typical solvent system

NH_3	:	THF	:	^{t}BuOH
2	:	1	:	1

- Liquid NH_3 (bp –33 ^{o}C) is used to dissolve metal, ether cosolvent (Et_2O or THF) is used to dissolve substrate, and a proton source ^{t}BuOH; EtOH; MeOH;  is used to quench the reaction.

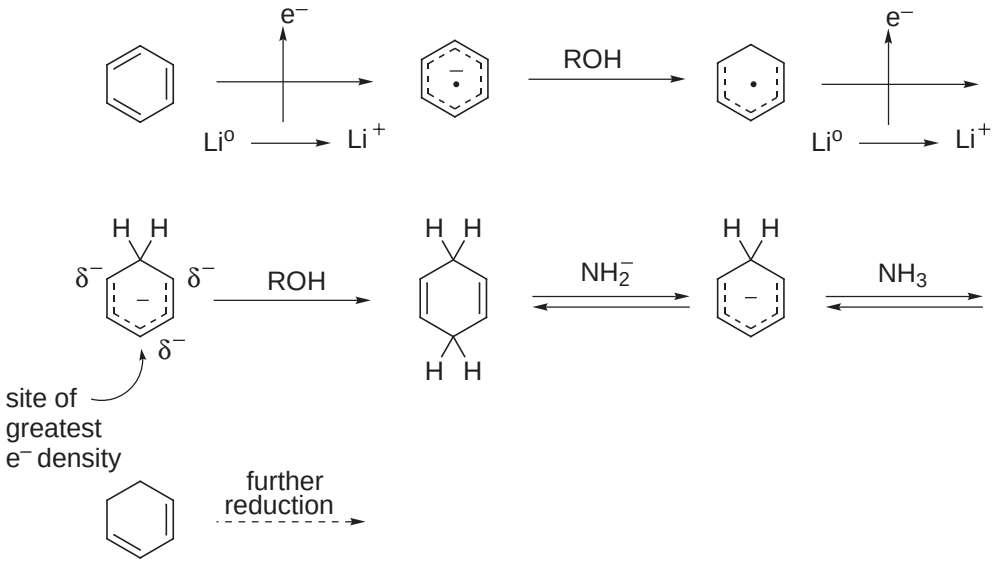
- If proton source is absent:



- Be sure to use an argon atmosphere, **not N_2** which forms lithium nitrides.

c. Mechanism

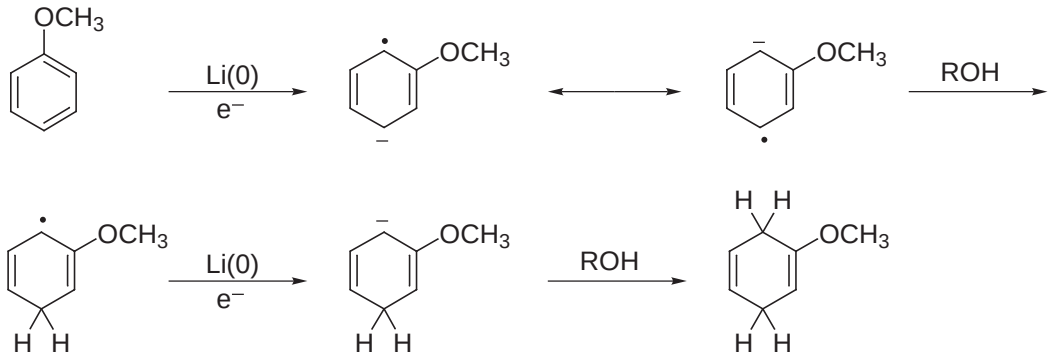
- Molecular Orbital Calculations: Radom *J. Am. Chem. Soc.* **1980**, *102*, 6430.

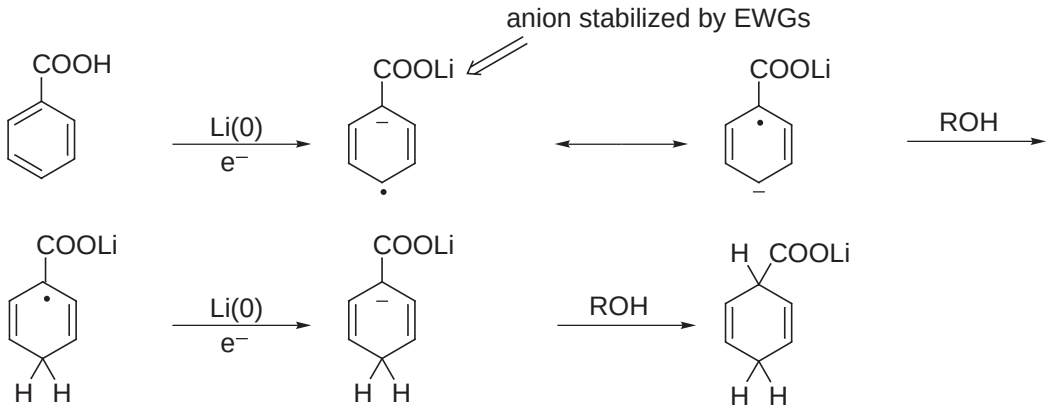


d. Regioselectivity

- Site of protonation of the radical anion is determined by site of maximum e⁻density.

- Radom *J. Am. Chem. Soc.* **1980**, *102*, 4074.





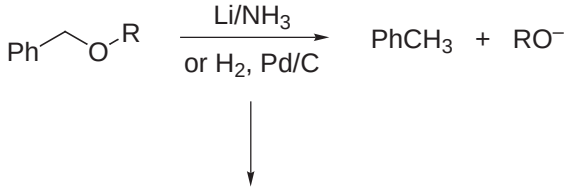
D = OH, OR, NR_2, SR, PR_2 (electron-donating groups)

W = COOH $\curvearrowright$ COO^-

$CONR_2$, $SiMe_3$, Ar (electron-withdrawing groups)

- but CO_2R, COR, CHO $\xrightarrow{Li/NH_3}$ $—CH_2O^-$, so they are part of donor (D) grouping.

e. Common application: hydrogenolysis



5 - 10% Pd on C as catalyst

H_2 can be replaced by $HCOONH_4$ or  as the source of H_2 and is a transfer hydrogenation: *Comprehensive Org. Syn.,* Vol. 8, 955.

f. Examples

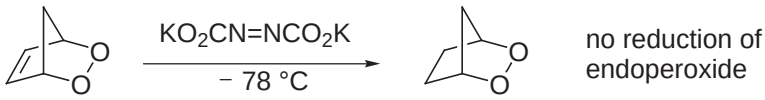
- From least hindered face of olefin

} complements H_2/cat.
same results but:
many functional groups are
stable to conditions/reagent

- *trans* > *cis* olefin (rate)
- Rate decreases with substitution of olefin
- C=O, NO_2, CN,  stable



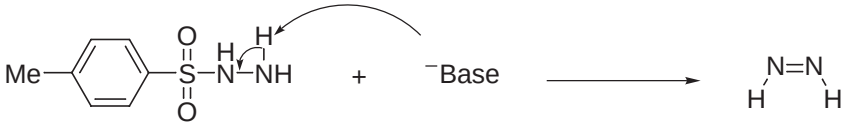
no reduction of endoperoxide

Adam *J. Org. Chem.* **1977**, *42*, 3987.

- Formation (generation) of reagents (diimide)

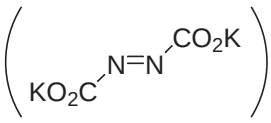
i. H_2O_2 /H_2NNH_2 old method

ii. recent method

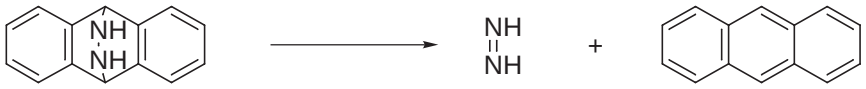


- related to McFadyen-Stevens Reduction.

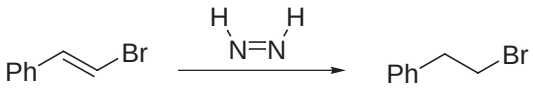
iii. $KO_2C{-}N{=}N{-}CO_2K$ $\xrightarrow[25\ °C,\ -CO_2\ (anhydrous)]{cat\ H^+}$ 



iv. retro Diels Alder reaction



- Example of use:

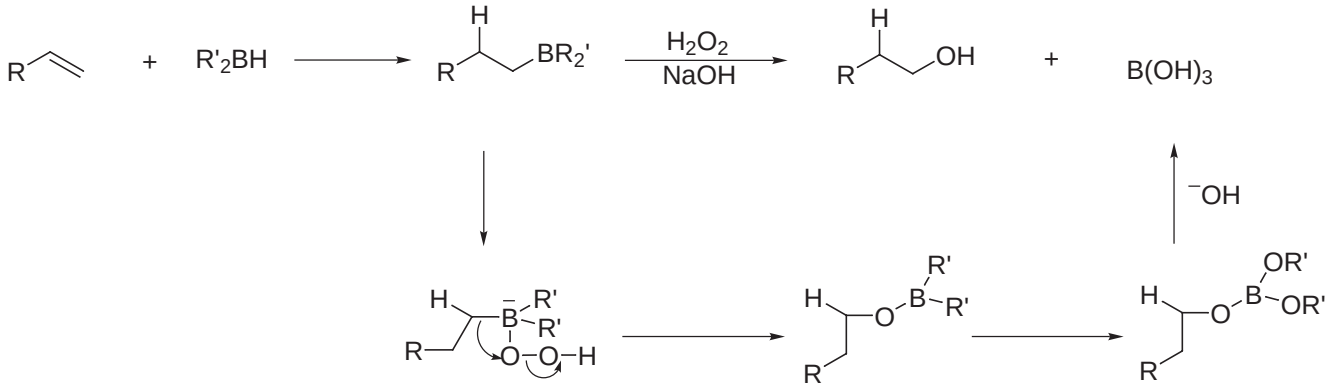


- Other reduction methods would give substantial debromination.

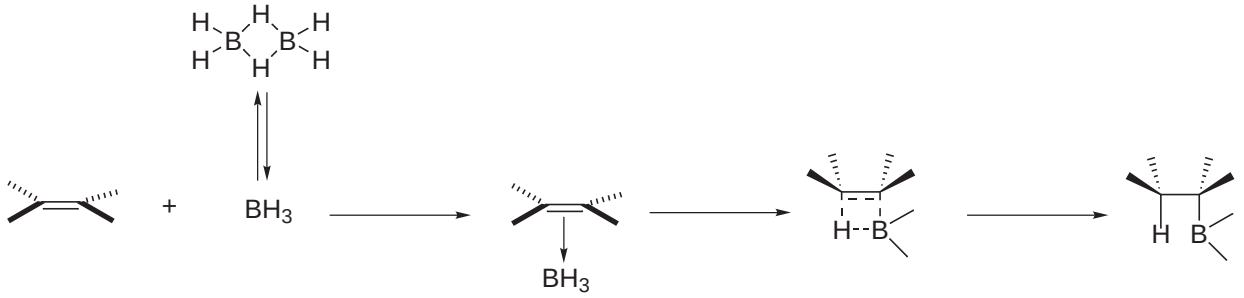
VII. Hydroboration - Oxidation (Reduction - Oxidation)

- Review: *Comprehensive Org. Syn.*, Vol. 8, pp. 703-732.

A. Mechanism



- anti-Markovnikov addition of H_2O to C=C



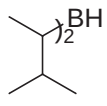
- rate

- Increased by electron-donating substituents on olefins.

- Increased by strain of olefins.

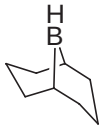
- Increased by decreased steric hinderance of olefins.

The reaction is characterized by a slight tendency for H (H^-) to add to carbon most capable of stabilizing a δ^+ charge or, in other words, for the nucleophilic carbon to attack the electrophilic B. However, it is also characterized by a nonpolar transition state where the rate of reaction and regioselectivity are determined principally by steric factors with unsymmetrical olefins.



diisoamylborane (Sia_2BH)

thexylborane ($ThxBH_2$)

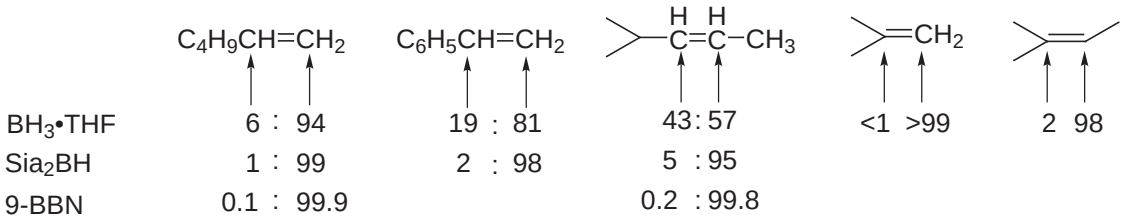


9-BBN

H. C. Brown (Purdue University) received the Nobel Prize in Chemistry (1979) for the discovery and development of the hydroboration reaction.

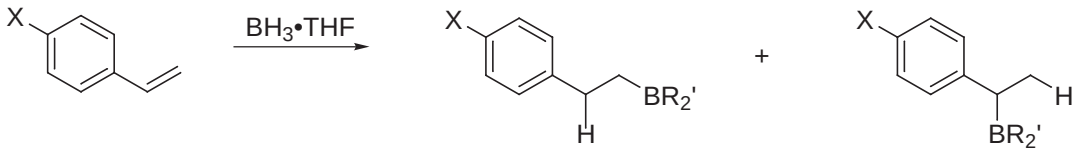
B. Regioselectivity

1. Steric Effects

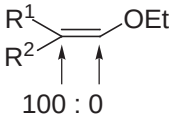


- diisoamylborane $\Longrightarrow$ larger than BH_3•THF and more selective.

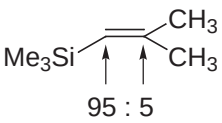
2. Electronic Effects

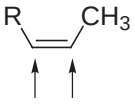


X = H	81	:	19
OCH_3	93	:	7
Cl	73	:	27
CF_3	66	:	34

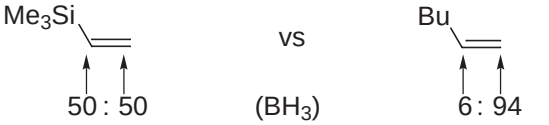


$R^1 = R^2 = Me$
$R^1 = R^2 = Et$



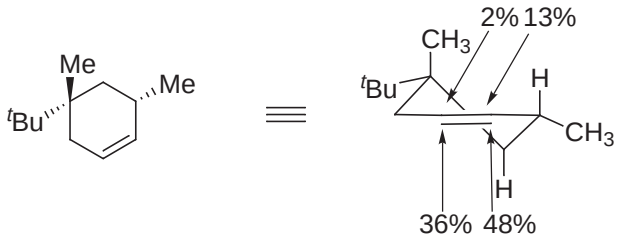


R = ^{i}Pr	43 : 57	BH_3
	5 : 95	Sia_2BH
R = $SiMe_3$	95 : 5	BH_3



C. Diastereoselectivity

1. Endocyclic Olefins

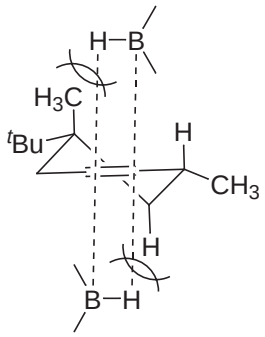


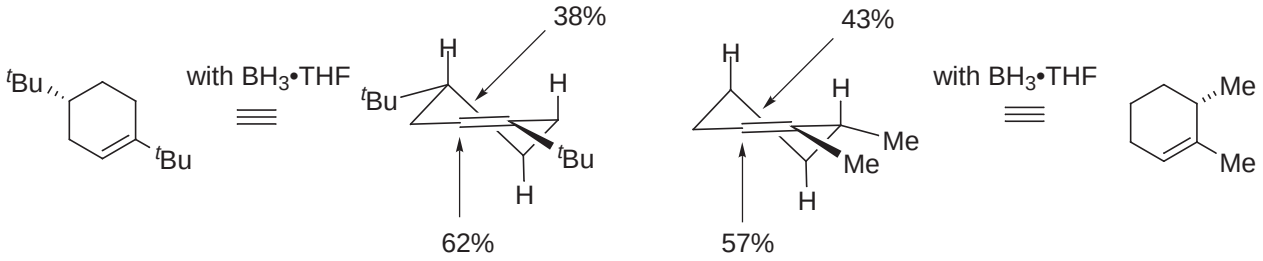
- predominant attack from least hindered face.

- *cis* addition

- from least hindered side

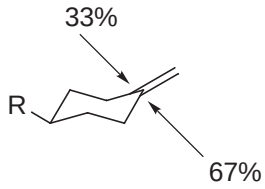
- least substituted position



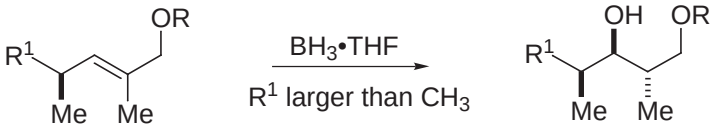


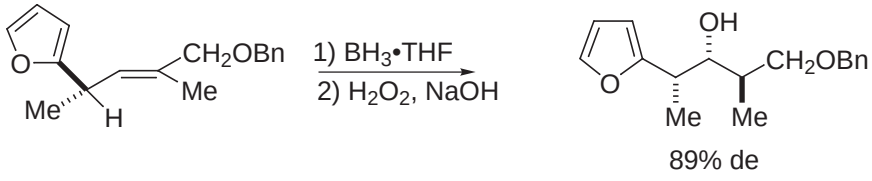
with BH_3•THF ⟹ Better with bulkier boranes

2. Exocyclic Olefins



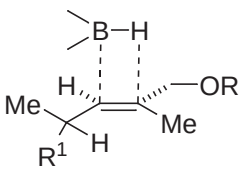
3. Acyclic Olefins





89% de

Kishi *J. Am. Chem. Soc.* **1979**, *101*, 259. (Monensin)



Considering the top case:
attack on least hindered
face of H-eclipsed conformation

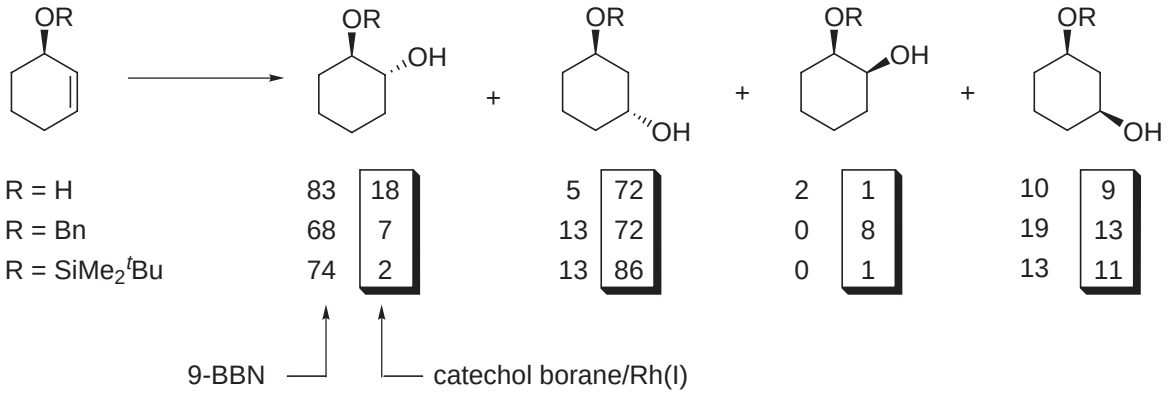
R^1/BH_2 interactions are worse
than Me/BH_2 interactions

Kishi *Aldrichim. Acta* **1980**, *13*, 23.

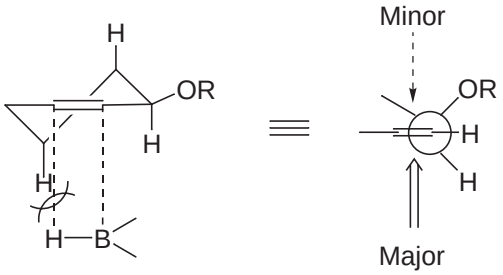
Burgess *Tetrahedron Lett.* **1989**, *30*, 395.

4. Allylic Alcohols and Ethers

- Cyclic allylic alcohols and ethers.



Evans *J. Am. Chem. Soc.* **1988**, *110*, 6917.



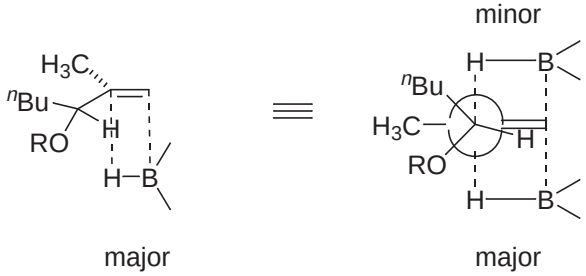
9-BBN reaction:

- Least hindered face opposite alkoxy group.
- Regioselectivity avoids a R_2B/H 1,3-diaxial interaction.

- Acyclic allylic alcohols and ethers

	syn	*anti*
R = H	8	92
R = TBDMS	11	89

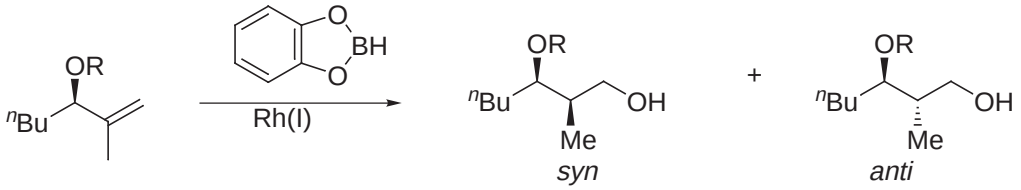
- Reaction takes place from H-eclipsed conformation and *cis* to the smaller OR group.



attack on face *syn* to smaller alkoxy substituent in the H-eclipsed conformation.

D. Metal-Catalyzed Hydroboration

- Diastereoselectivity can be reversed with catecholborane and Rh(I) catalyst (i.e., Wilkinson's catalyst).



R = H	75	25
R = TBDMS	96	4

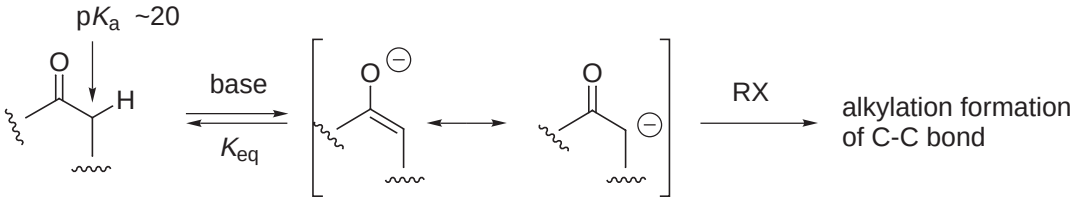
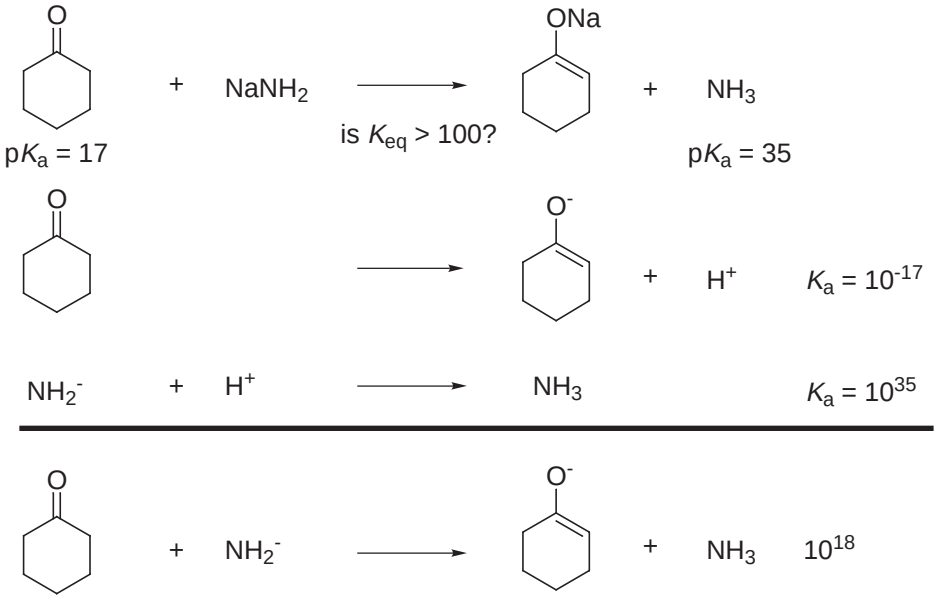
Hydrazones:	*Comprehensive Org. Syn.,* Vol. 2, 503.

A. Acidic Methylene Compounds (i.e., Malonates)

- α-Deprotonation



- Use of a base which stoichiometrically deprotonates the ketone completely: (i.e. $K_{eq} > 100$)



Therefore, a good deprotonation (essentially all ketone deprotonated)
Note: need to have pK_a difference of 2 pK_a units to get $K_{eq} = 100$.

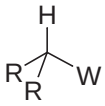
1. Estimation of pK_a

W = Cl inductive stabilization

W =  , NO_2, etc. resonance stabilization

 pK_a = 20;  pK_a = 45;  pK_a = 35-37

- an increase in acidity of H results in a *faster* deprotonation (kinetic effect) as well as a stabilization of anion formed (thermodynamic effect).

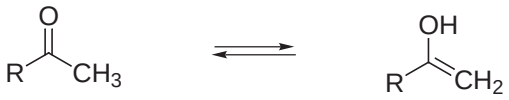


Group (-W)	pK_a effect (units)	Note
alkyl	~1-2 ↑ (decrease in acidity)	both due to inductive effects
halogen	~1-2 ↓	
	~5-7 ↓	both depend on favorable orbital overlap to allow resonance stabilization
	~5-7 ↓	
RS—	~3-5 ↓	

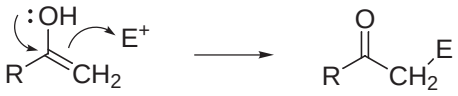
Others: NO_2 > COR > SO_2R > CO_2R, CN > SOR, Ph

Compound	pK_a	Note
	20	
	13	ketone better enolate stabilizer than ester
	11	
	9	
	5	~same as acetic acid
H_2O	14	
	25	
	15	

2. Ketone-Enol Tautomerism



- generally << 1% enol



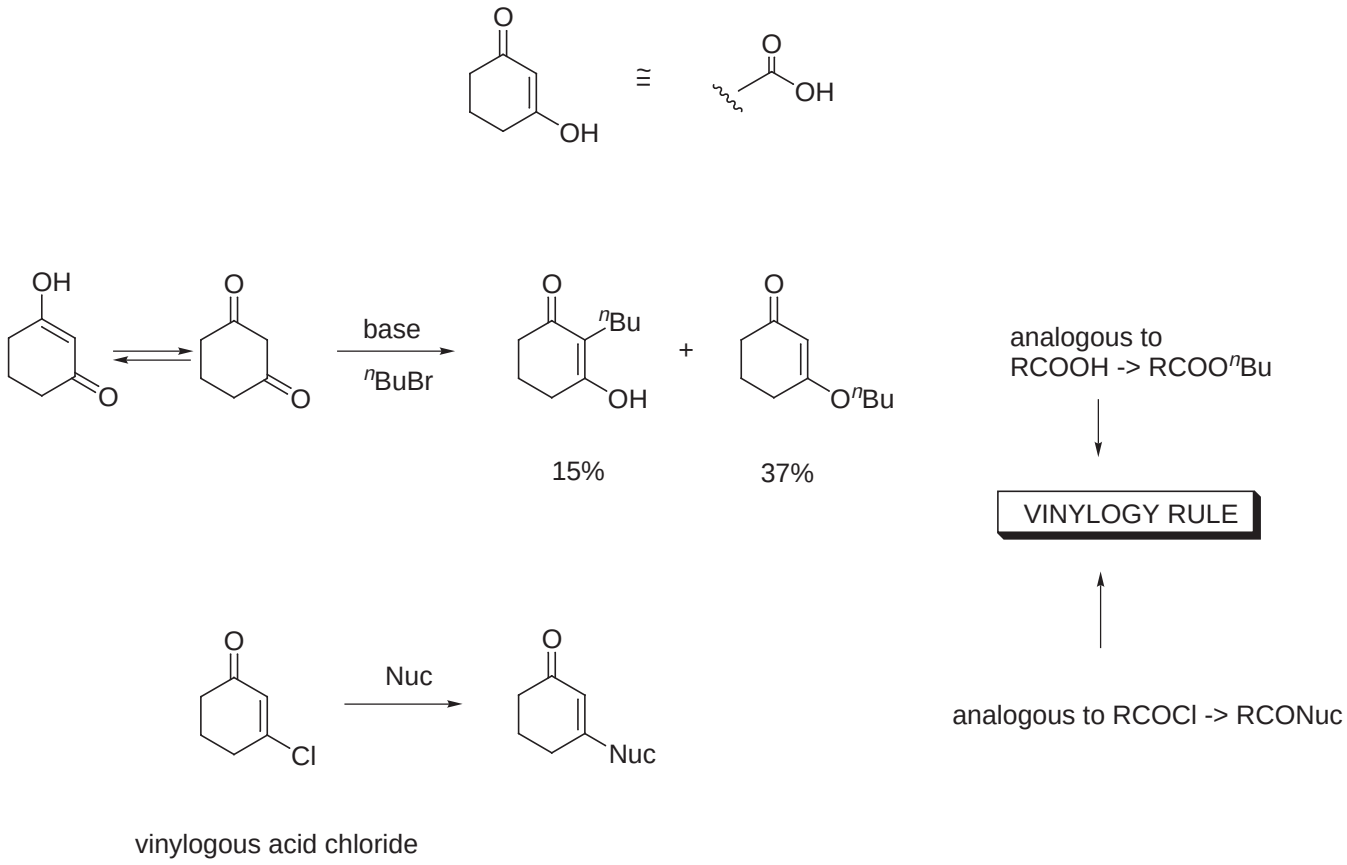
<< 1%

- Usually not likely to form a bond with an electrophile since not present in high concentration
- However, some ketones do exist in high enol concentration and react via enol

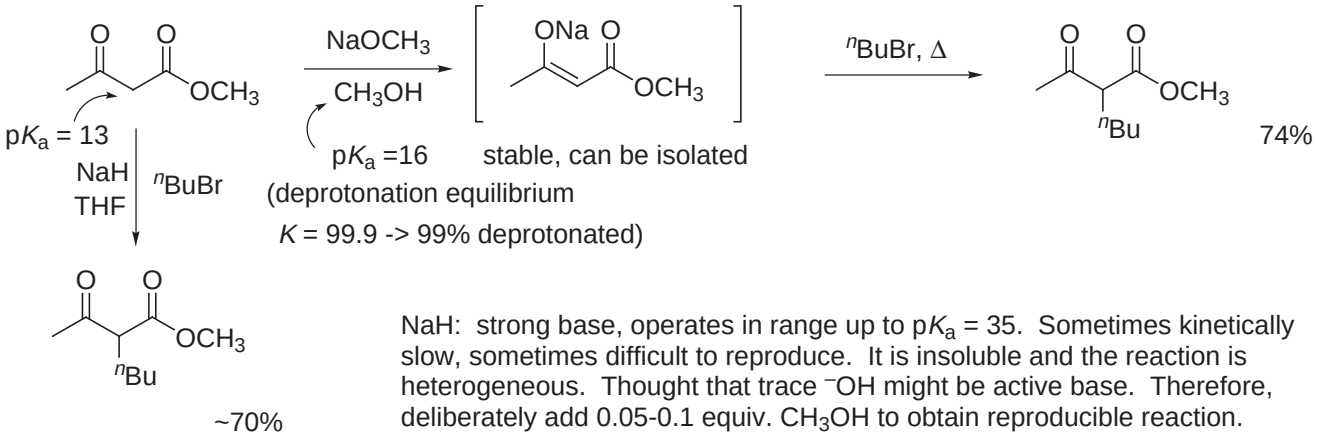
Compound	Enol content
	0.0004%
	< 0.002%
	40% (neat) 60% (EtOH)
	100%(neat) 95% (H_2O) 2-14% (cyclohexane)
	10-13% (EtOH) 50% (cyclohexane) ← intramolecular H-bond
	16% (H_2O) 63% (EtOH) 92% (cyclohexane) ← intramolecular H-bond
	3% (H_2O) 31% (EtOH) 55% (cyclohexane) ← intramolecular H-bond

- If a compound has a vinyl spacer, the reactivity parallels that of the parent compound.

1,3-Cyclohexadione in its enol form is a vinylogous carboxylic acid and it exhibits many properties of a RCOOH, including low pK_a, O-alkylation.

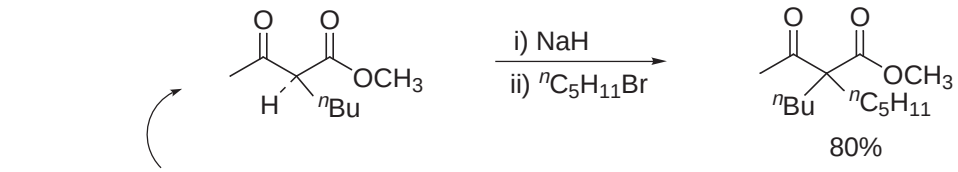


3. Acetoacetic Ester Synthesis



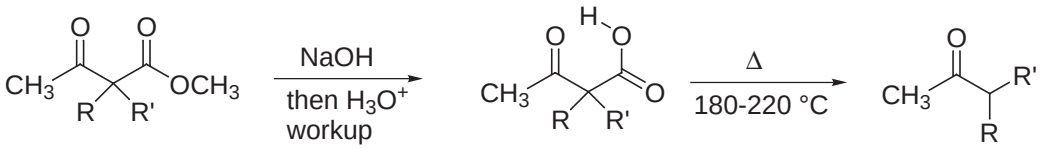
NaH: strong base, operates in range up to pK_a = 35. Sometimes kinetically slow, sometimes difficult to reproduce. It is insoluble and the reaction is heterogeneous. Thought that trace $^-$OH might be active base. Therefore, deliberately add 0.05-0.1 equiv. CH_3OH to obtain reproducible reaction.

- The product can be further alkylated:

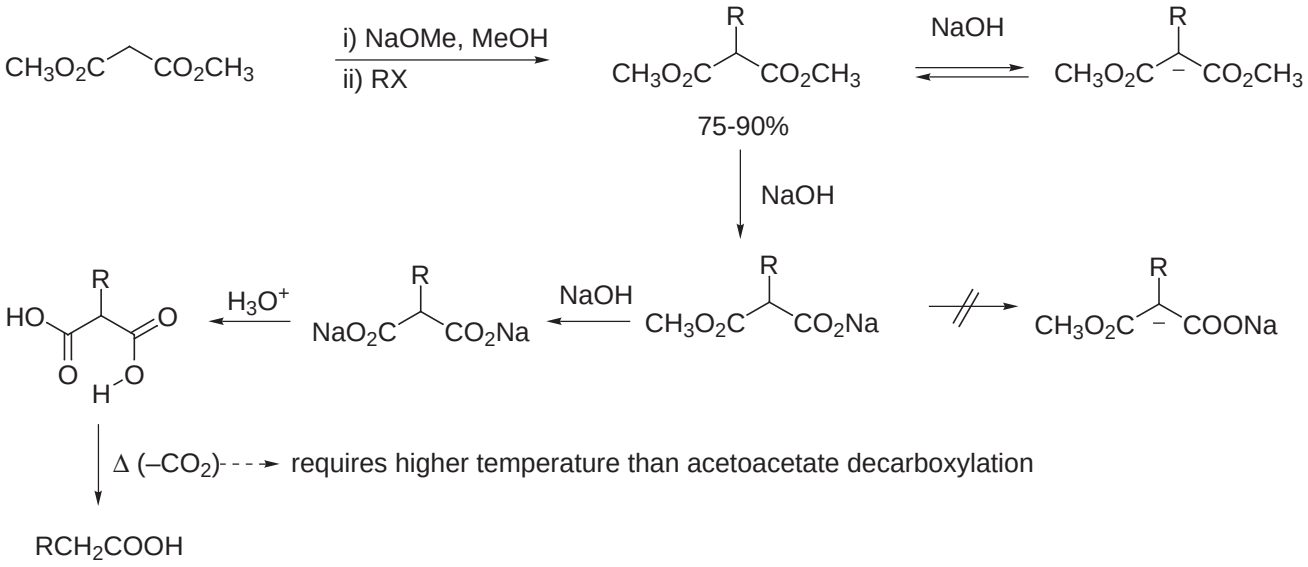


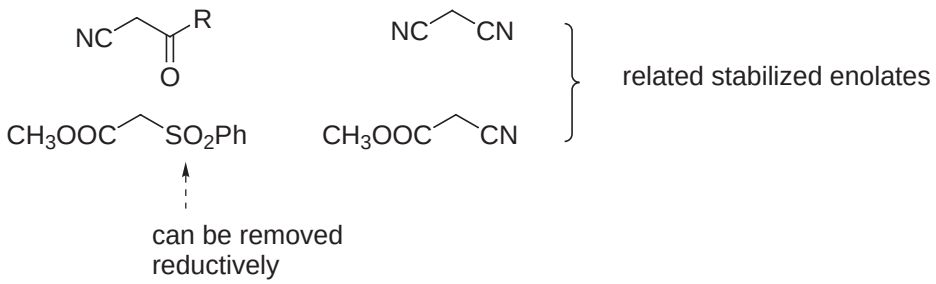
pK_a now 1-2 units higher than parent ⟹ concentration of parent enolate vs. concentration of product enolate in monoalkylation reaction is very high (> 90:10) -> monoalkylation fairly clean.

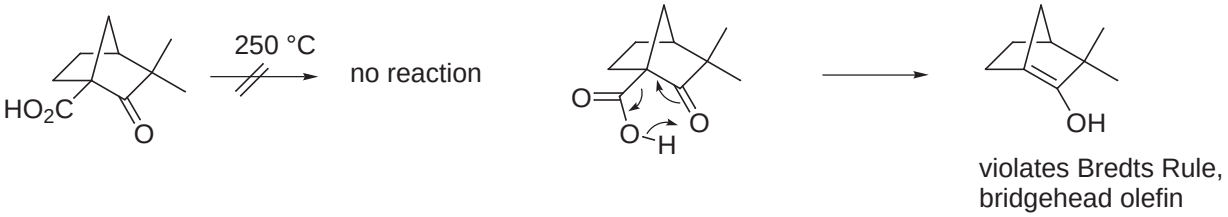
- Hydrolysis and decarboxylation gives α-substituted ketones:



4. Malonic Ester Alkylation

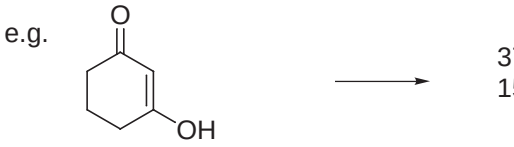


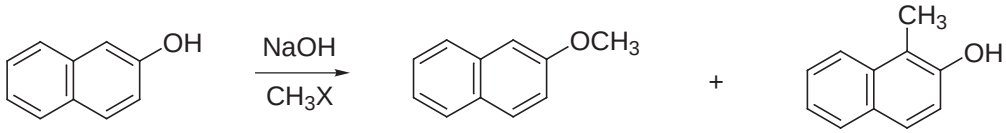




5. Enolates: *C*- vs. *O*-Alkylation

- Ketones which are more acidic tend to give more *O*-alkylation.





- The more reactive the alkylating agent, the more *O*-alkylation observed

X = I	66	:	33
X = OTs	100	:	0

- Rarely see *O*-alkylation of ketone enolates
  often see *O*-alkylation of stabilized enolates
  e.g., β-diketones and β-keto esters

localized, harder anion

softer, more diffuse anion

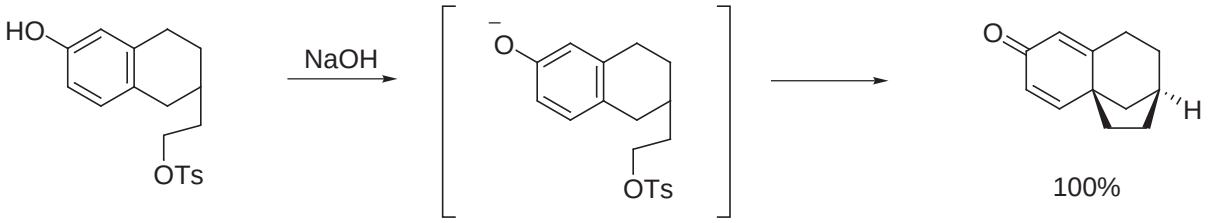
- tends to react with harder electrophiles (CH_3OTs, $Me_3^+OBF_4^-$)

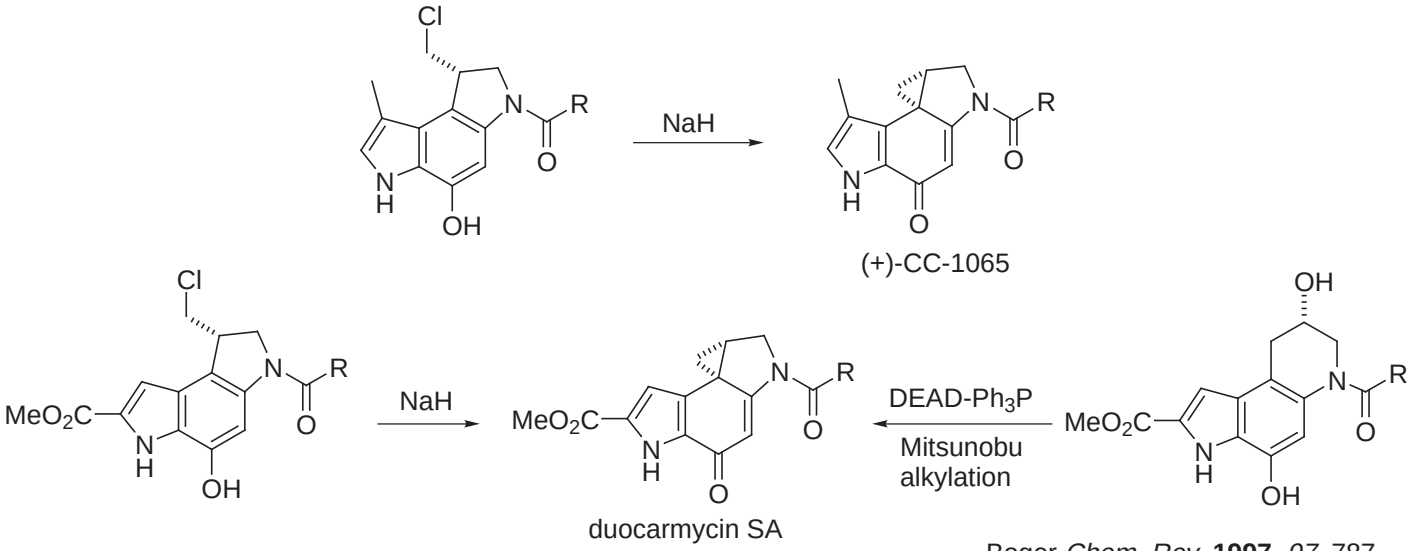
reacts with softer alkylating agents (RI, RBr)

Meerwein's salt

more reactive or more ionized = harder

- Intramolecular constraints can affect course of *C*- vs. *O*-alkylation





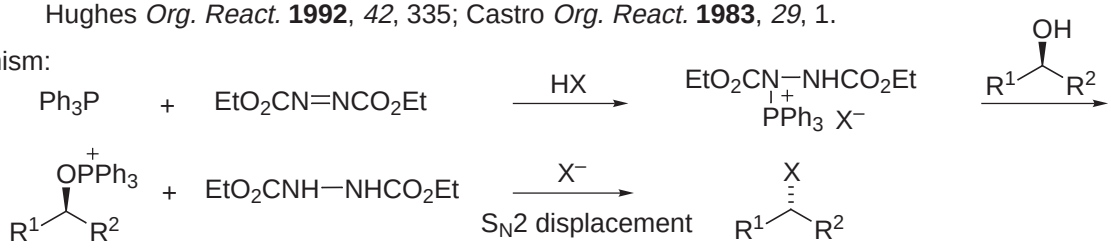
Boger *Chem. Rev.* **1997**, *97*, 787.

- Mitsunobu alkylation

Mitsunobu, Yamada, Mukaiyama *Bull. Chem. Soc., Jpn.* **1967**, *40*, 935.

Review: Mitsunobu *Synthesis* **1981**, 1.
Hughes *Org. React.* **1992**, *42*, 335; Castro *Org. React.* **1983**, *29*, 1.

- Mechanism:

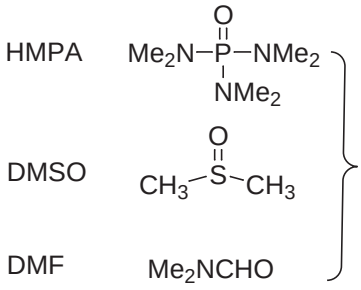


HX: pK_a typically <15 (RCO_2H, phenols, imides, malonates, β-keto esters)

Related reagents including Ph_3P/CCl_4, Ph_3P/NXS are used to convert an alcohol to the corresponding halide.

- Factors which favor *O*-alkylation

1. Polar solvent:



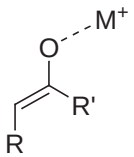
polar, aprotic solvents:

a. separate metal cation from enolate oxygen, making oxygen more free to react

b. coordinate electrophile, activate and increase their reactivity

c. increase rate of reaction

2. Large, noncoordinating metal cation:



- again, frees up oxygen to react

$M^+ = R_4N^+ > K^+ > Na^+ > Li^+$

O-alkylation ⇢⇠ *C*-alkylation

rate of reaction

ion pair
separation of charge, harder
more reactive anion

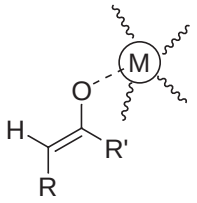
lithium essentially covalently coordinated to O

3. Aggregation/Solubility:

Homogeneous, monomeric enolates ⟶ *O*-alkylation

Heterogeneous, aggregate enolates ⟶ *C*-alkylation

Li enolates tend to be more aggregated



hard for RX to get to O atom, so reacts at C

4. Structure of alkylating agent

a. Leaving group:

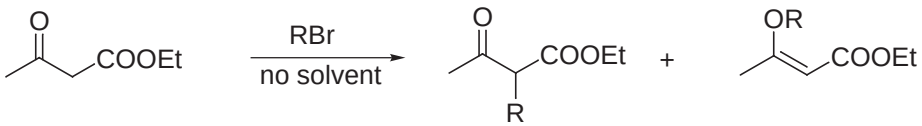
(hard alkylating agents) (soft alkylating agents)

for R-X: X = Me_3O^+ > OTs > Cl > Br > I

O-alkylation ⟶ *C*-alkylation

	Solvent	X	*C*- : *O*-alkylation rel % products
O-alkylation ↓ Polarity of solvent ↓	acetone	Cl	90 : 10
	CH_3CN	Cl	81 : 19
	DMSO	Cl	53 : 47
For *C*-alkylation: I > Br > Cl	DMF	Cl	54 : 46
	DMF	Br	67 : 33
	DMF	I	>99 : 1

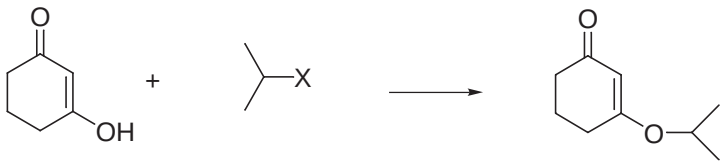
b. Degree of substitution of alkylating agent:



$^nC_3H_7Br$	97	:	3
more sterically hindered, so "harder" ⟶ 	73	:	27

,

mainly *C*-alkylation



works well in polar, aprotic solvents (ie., HMPA, DMSO), or even K_2CO_3, acetone will work

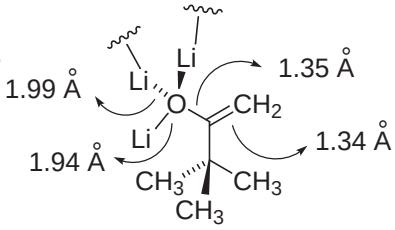
B. Enolate Structure

- Actually exist as higher aggregates in solution: dimer-tetramer.
- Originally suggested by House *J. Org. Chem.* **1971**, *36*, 2361.
- Supported by NMR studies: Jackman *Tetrahedron* **1977**, *33*, 2737.
- Confirmed by X-ray: Dunitz *Helv. Chim. Acta* **1981**, *64*, 2617.

see also:

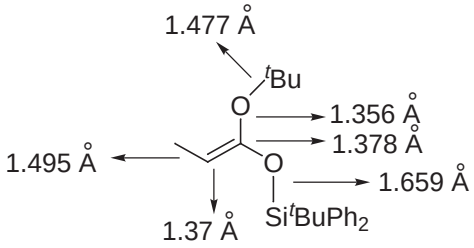
Seebach *J. Am. Chem. Soc.* **1985**, *107*, 5403.

Lynch *Tetrahadron Lett.* **1989**, *30*, 447.

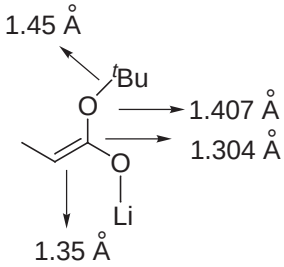


tetramer aggregates

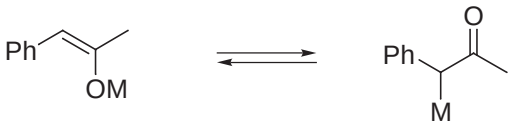
bond lengths, angles much like those of enol ether.



vs



Ketone Enolates:

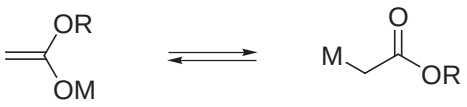


Note: not really an equilibrium; these are resonance structures.

K_{eq} < 1 for most metals (Li, Na, K, MgX, ZnX) ⟶ negative charge, M^+ on oxygen.

> 1 for M = HgI

Ester Enolates:

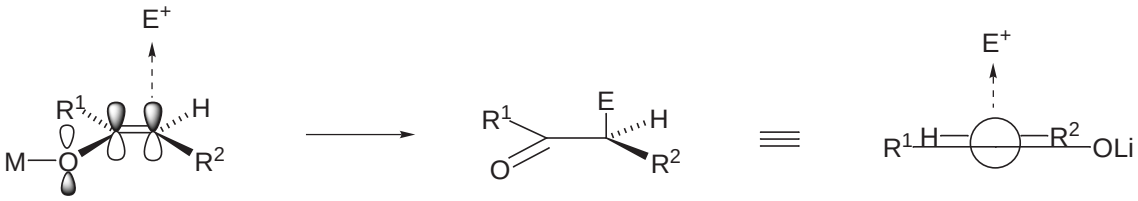


K_{eq} < 1 for Li K_{eq} > 1 for ZnBr (Reformatsky reagents)

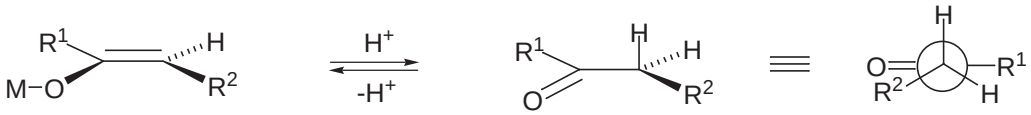
C. Enolate Alkylations: π-Facial Stereoselectivity

1. Stereoelectronic Effects

- The attacking electrophile must obey the principle of maximum overlap of the participating orbitals by perpendicular approach to the plane of atoms which constitute the enolate (enol) function.



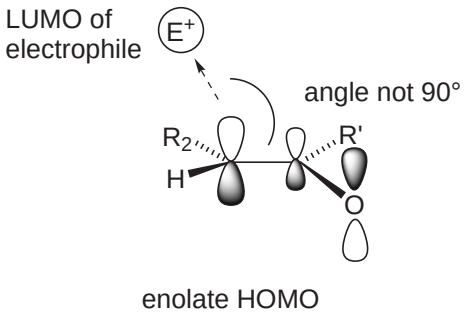
- Also applies to protonation in reprotonation reaction:



- Nucleophilic addition to carbonyl compound takes place not at 90° (perpendicular) but at an angle of 105 ± 5°

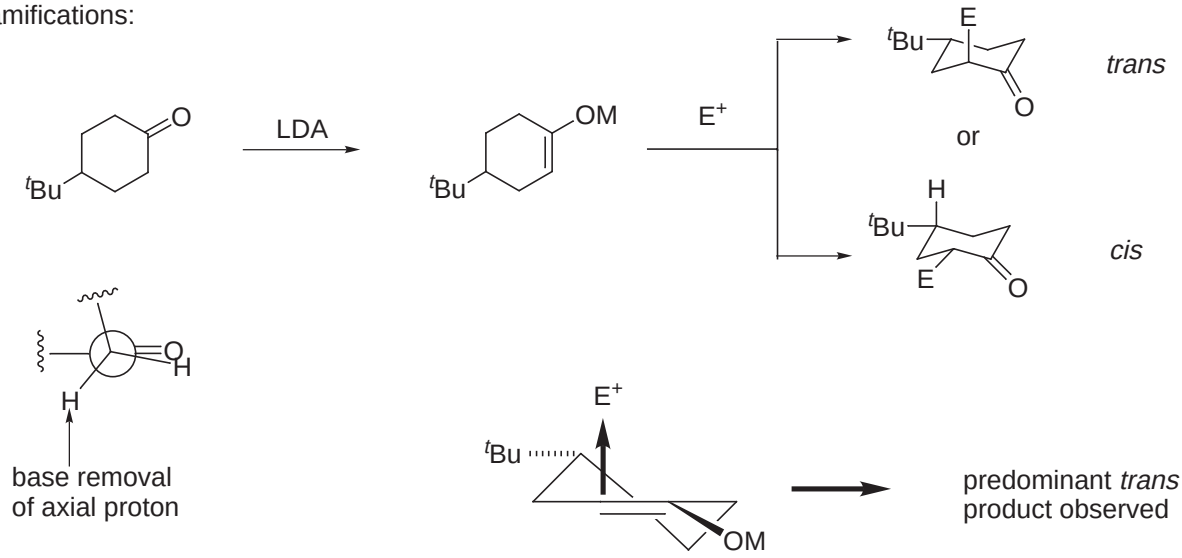
Dunitz *Tetrahedron* **1974**, *30*, 1563.

- Same applies to enolate alkylations

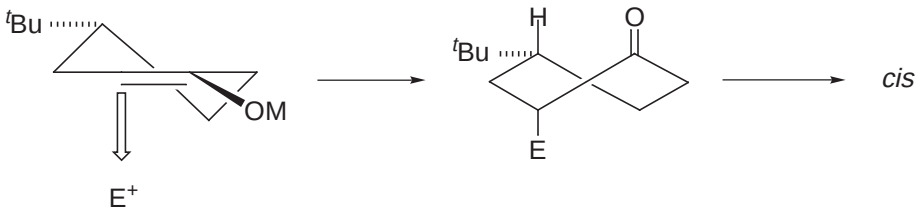


enolate HOMO

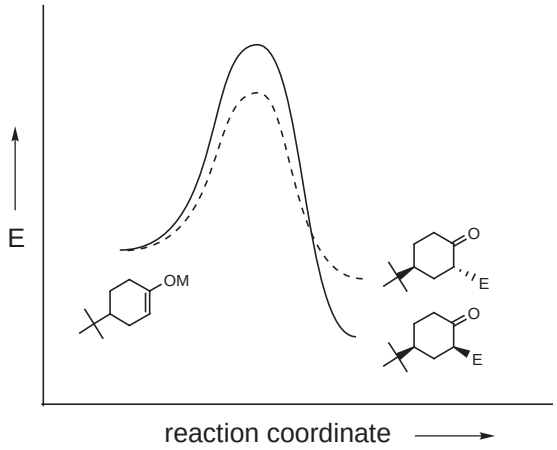
- Ramifications:



- In order to get *cis*, must proceed through a boat-like T.S.!



- Therefore



Energy of activation for formation of the more stable *cis* product is higher because it involves a boat-like T.S.

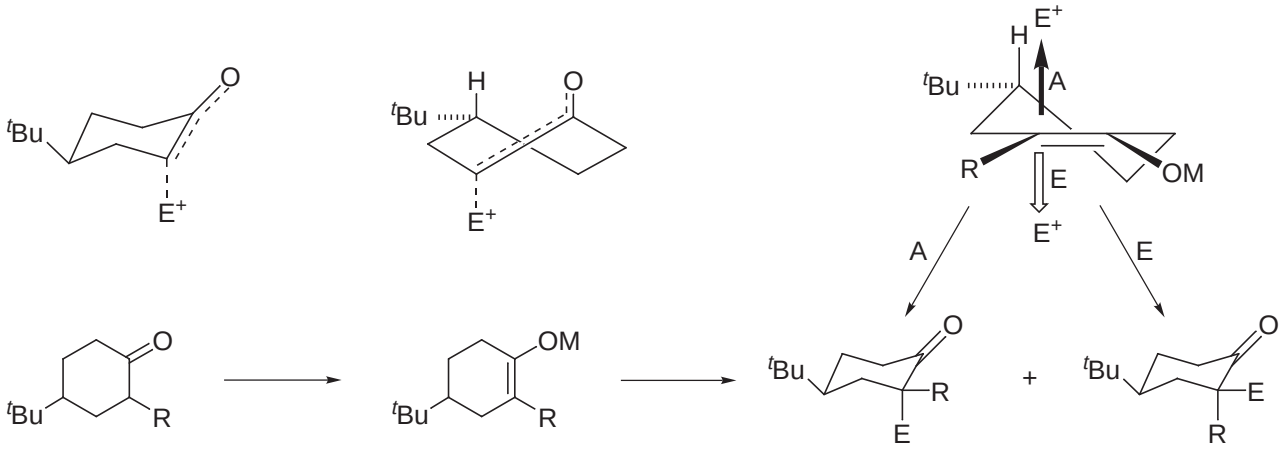
Corey, Sneen *J. Am. Chem. Soc.* **1956**, *78*, 6269 (origin of axial alkylation).
They also introduced the term stereoelectronic effect to describe this behavior.

This was the pioneering work that led to the now widespread predictions about reactions and reaction products based on orbital alignment or overlap and provided the term "stereoelectronic" effect.

- Examples of stereoelectronic control

axial alkylation
chair-like transition state

equatorial alkylation
via twist boat T.S.



House *J. Org. Chem.* **1968**, *33*, 935.
Caine *J. Org. Chem.* **1969**, *34*, 3070.

M	R	E	axial		equatorial
Li	H	$Et_3O^+BF_4^-$	51	:	49
Li	H	EtI	54	:	46
Li	H	MeI	55	:	45
Li	H	DOAc	70	:	30
Li	Et	HOAc	80	:	20
Li	Me	CD_3I	70	:	30
Li	CN	CH_3I	77	:	23
Li	$COOCH_3$	CH_3I	83	:	17

less reactive enolates
(so more selective)

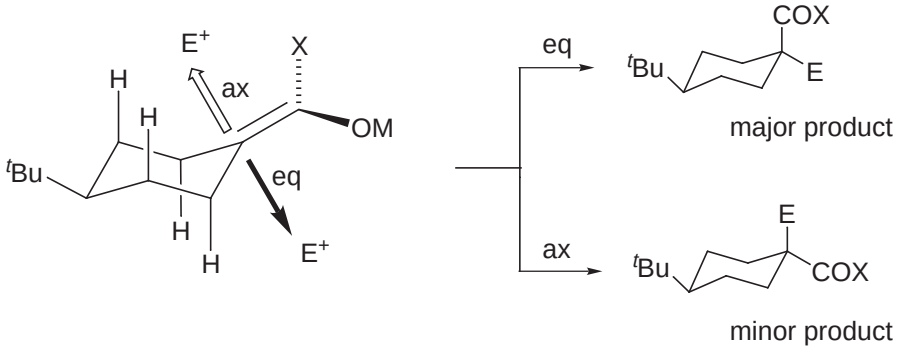
Kuehne *J. Org. Chem.* **1970**, *35*, 161, 171.

2. Steric Effects

- Stereoelectronic effects equivalent for exocyclic enolates.
- Relatively insensitive to alkylating agent and conditions.

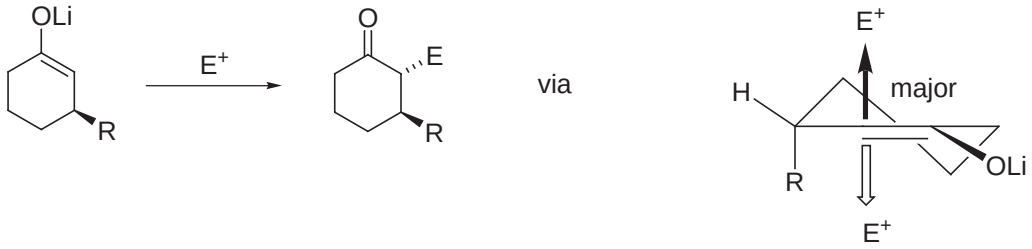
Behavior as a large reagent preferring equatorial delivery.

- Transition states for enolate alkylations are thought to be REACTANT-LIKE.



X	E		eq : ax
CH_3	MeI	25 °C	85 : 15
OCH_3	MeI	–78 °C	84 : 16
OCH_3	^{n}BuBr	–78 °C	87 : 13

House *J. Org. Chem.* **1968**, *33*, 943.
Krapcho *J. Org. Chem.* **1980**, *45*, 3236.

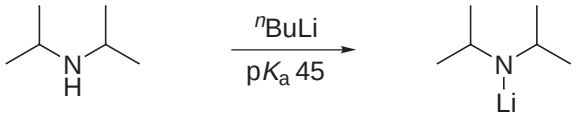


D. Enolate Generation

1. Soluble Bases

- $NaNH_2$, $LiNH_2$, KNH_2 ⟶ strong bases, but insoluble in conventional organic solvents

- Soluble secondary amine derived bases



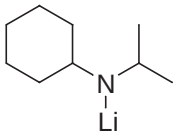
= LDA

pK_a = 35

readily available, soluble; amine byproduct is low MWt, volatile, and easily removed. The anion is also nonnucleophilic (relatively hindered)

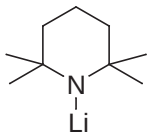
- Aggregates: Williard *J. Org. Chem.* **1993**, *58*, 1.

- Other widely used bases:



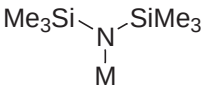
= Lithium isopropylcyclohexylamide (LICA)

very hindered base



= Lithium 2,2,6,6-tetramethylpiperidide ("FAT ALBERT", LTMP)

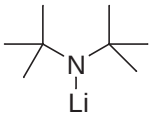
very hindered



M = Li Lithium hexamethyldisilazide (LHMDS or LHDS)

= Na Sodium hexamethyldisilazide (NaHMDS)

= K Potassium hexamethyldisilazide (KHMDS)



now available

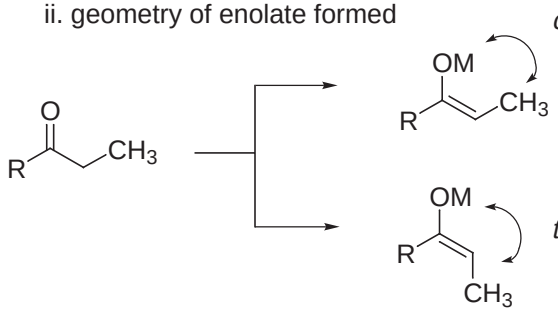
potassium bases not as effective for kinetic enolate generation. ----→

5. Acyclic Carbonyl Compounds

- Two issues: i. site of deprotonation
ii. geometry of enolate formed

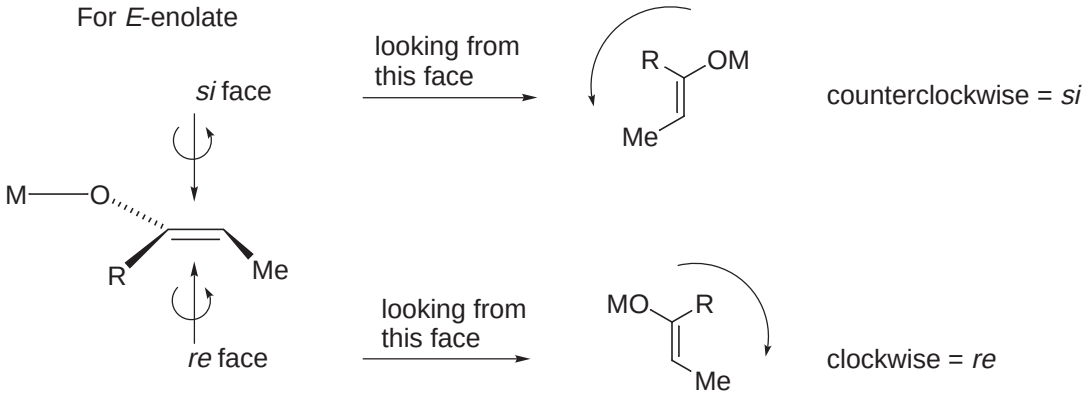


Z-enolate (Zusammen)

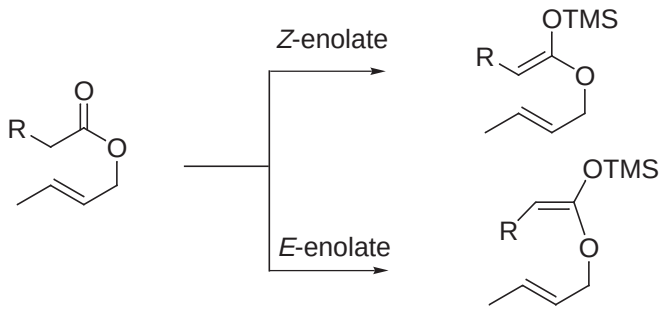
E-enolate (Entgegen)

- Also: the enolate has two diastereotopic faces:

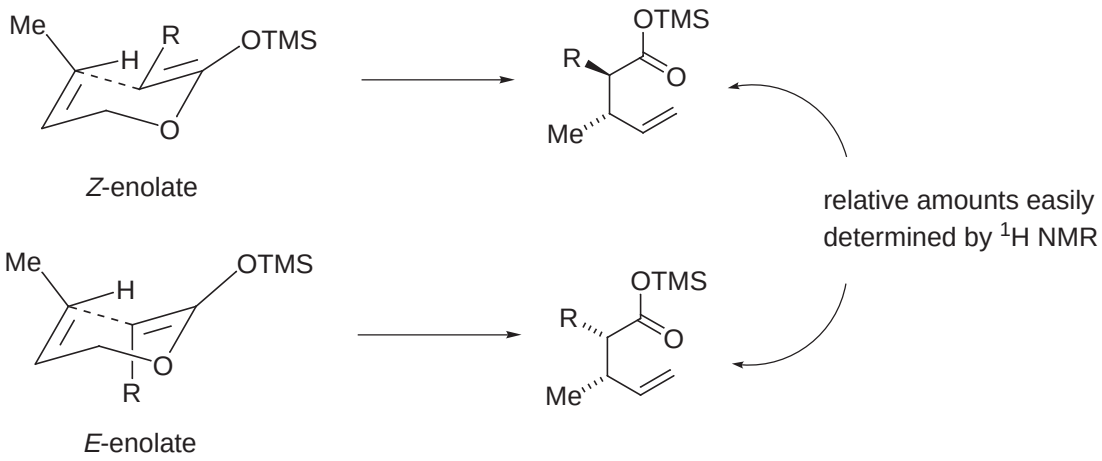
For *E*-enolate



- ASIDE: Geometry of enolate can be determined by Claisen rearrangement:



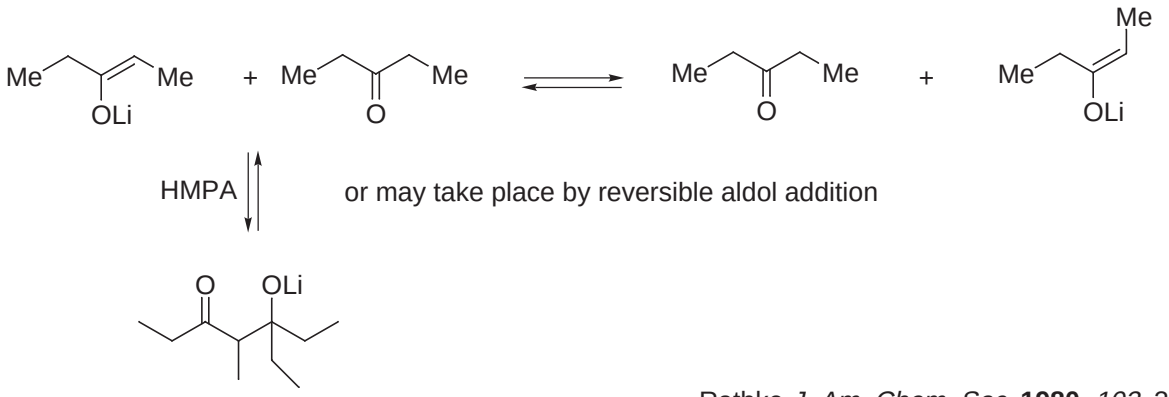
- Claisen rearrangement known to proceed through *chair-like* T.S.:



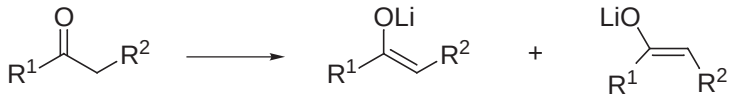
A. Acyclic Ketones

	Base	*Z*		*E*	
very hindered amide base ----→	LTMP (–78 °C)	14	:	86	← kinetic enolate
	LTMP/HMPA	92	:	8	← thermodynamic enolate
	LDA	23	:	77	
	LICA	35	:	65	
	LHMDS	66	:	34	
	$(PhMe_2Si)_2NLi$	100	:	0	

- Thermodynamic enolate formation



Rathke *J. Am. Chem. Soc.* **1980**, *102*, 3959.



Z-enolate *E*-enolate

R^1	R^2		*Z*	*E*	
Et	Me	LDA	23	77	
Et	Me	LTMP	14	86	
Et	Me	LTMP-LiBr	2	98	← best conditions for *E*-enolate (kinetic)
^{i}Pr	Me	LDA	37	63	
^{i}Pr	Me	LTMP	33	67	
^{i}Pr	Me	LTMP-LiBr	5	95	
^{t}Bu	Me	LDA	98	2	
^{t}Bu	Me	LTMP	95	5	
^{t}Bu	Me	LTMP-LiBr	95	5	← *Z*-enolate only very large R^1
Me	Ph	LDA	7	93	
Me	Ph	LTMP	8	92	
Me	Ph	LTMP	3	97	

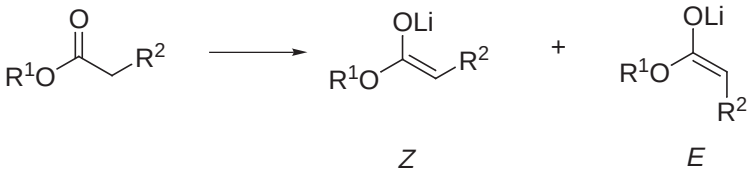
Note: As R^1 becomes sterically more demanding, *Z*-enolate increases or predominates even under kinetic conditions.

Note: As R^2 becomes sterically more demanding, *E*-enolate selectivity increases under kinetic conditions: Ph > Me.

Collum *J. Am. Chem. Soc.* **1991**, *113*, 9571.

B. Acyclic Esters

- Similar to ketones:



Z *E*

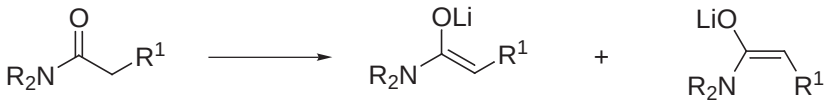
C. Acyclic Amides

give only *Z*-enolate

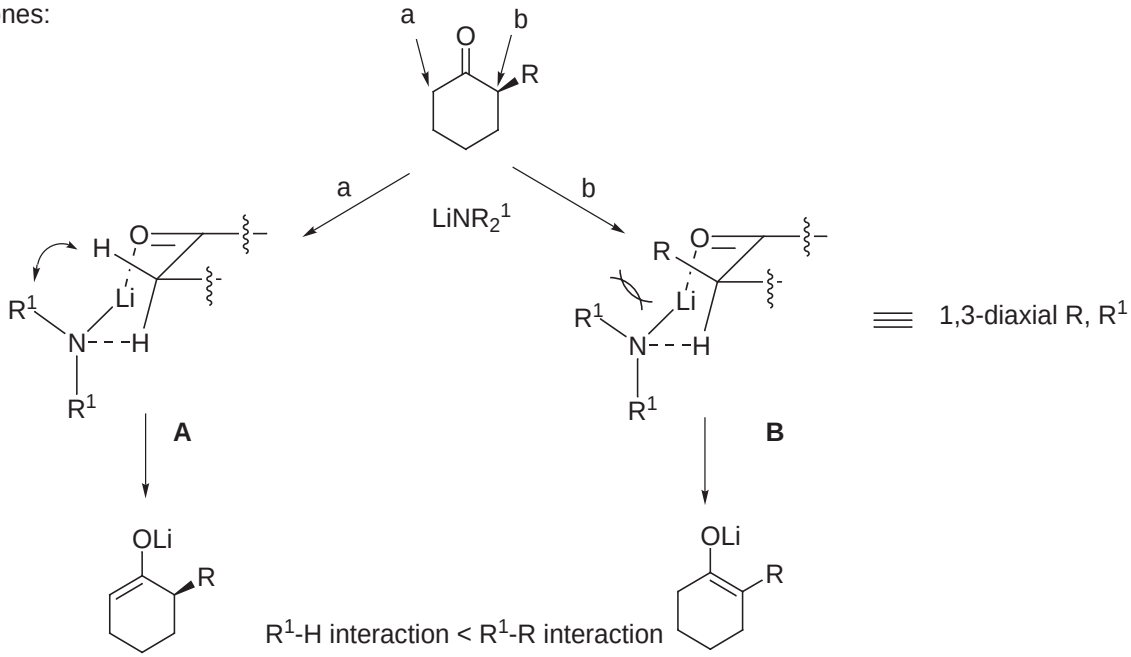


Z-enolate *E*-enolate

R	R^1	base	*Z*		*E*
Et	CH_3	LDA	>97	:	3
$(CH_2)_4$	CH_3	LDA	>97	:	3

6. Ireland Transition State Model for Deprotonation *J. Am. Chem. Soc.* **1976**, *98*, 2868.

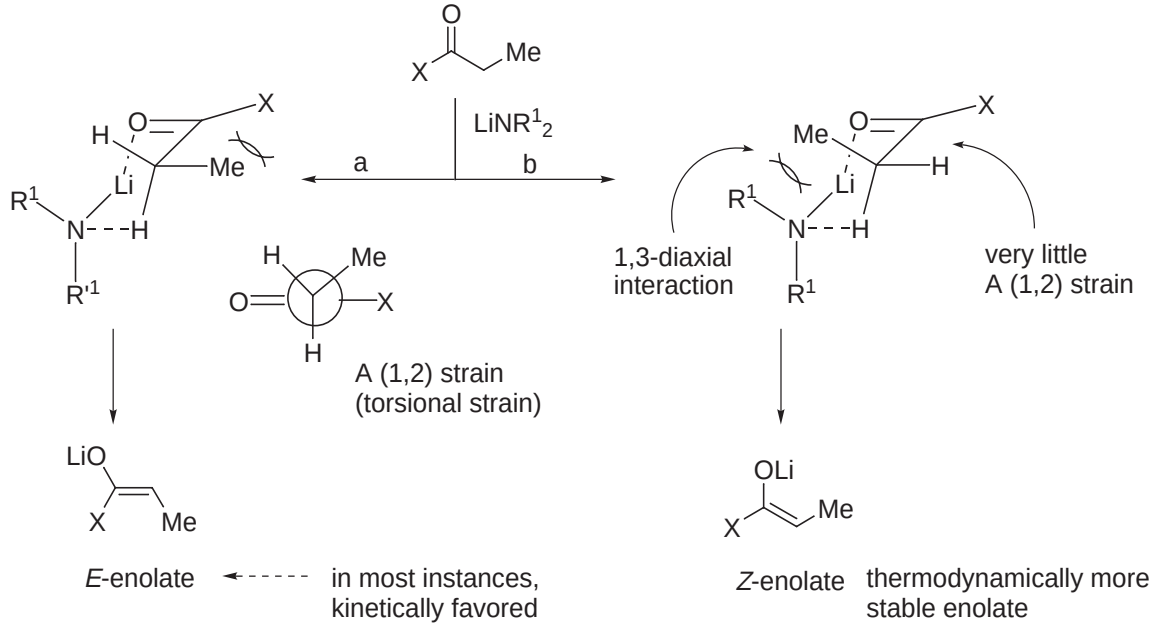
- For Cyclic Ketones:



ketone	base	**A** vs. **B**	1,3-diaxial interaction
R = CH_3	LDA	99 : 1	^{i}Pr, CH_3
Ph	LDA	>99 : 1	^{i}Pr, Ph
OCH_3	LDA	85 : 15	^{i}Pr, OCH_3
NMe_2	LDA	98 : 2	^{i}Pr, NMe_2

- More hindered bases (^{t}Bu_2NLi, LiHMDS, LTMP) would increase selectivity for kinetic enolate formation (1,3-diaxial interactions even larger in T.S. for thermodynamic enolate formation)

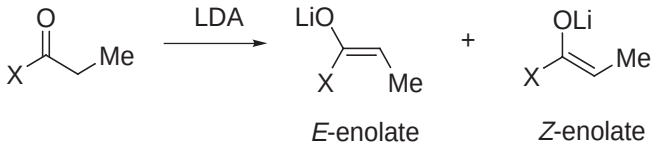
- For Acyclic Ketones, Esters, and Amides:



E-enolate ⟵ in most instances, kinetically favored

Z-enolate thermodynamically more stable enolate

- Example:



E-enolate *Z*-enolate

X	LDA	*E* : *Z*	
OCH_3		95 : 5	Me/R^1 1,3-diaxial interaction worse than Me/X A (1,2) interaction
O^{t}Bu		95 : 5	
Et		77 : 23	
^{i}Pr		40 : 60	
^{t}Bu		0 : 100	X getting larger, so A (1,2) steric interaction outweighs the Me/R^1 1,3-diaxial interaction
Ph		0 : 100	
NEt_2		0 : 100	

- NOTE: model only applicable for conditions which would promote coordination of base (Li cation) with carbonyl. It breaks down with polar solvents, crown ether, HMPA conditions for deprotonation.

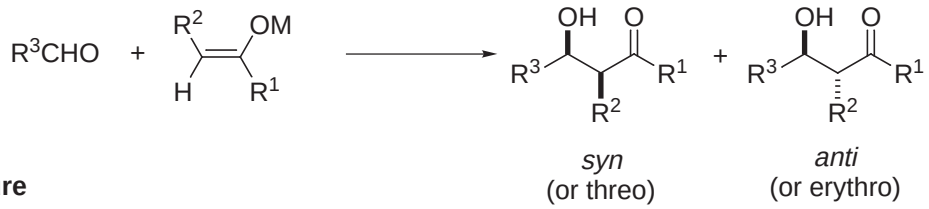
ee (%)	99	95	99	91

Additional examples of asymmetric alkylations may be found in the sections discussing enolate equivalents.

G. Aldol Addition (Condensation)

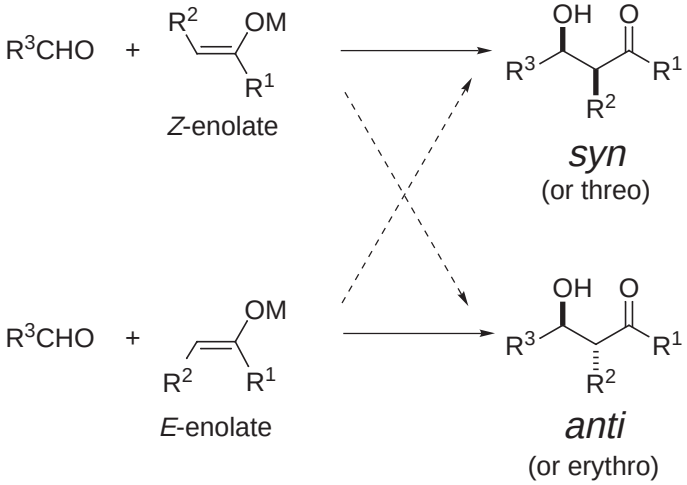


syn (or threo) *anti* (or erythro)

1. Nomenclature

syn/*anti*	*J. Am. Chem. Soc.* **1981**, *103*, 2106. (supercedes erythro/threo nomenclature)
erythro/threo	*Angew. Chem., Int. Ed. Eng.* **1980**, *19*, 557.
Summary	*Asymm. Synth.* Vol. 3, pp. 111-212. (Review of aldol diastereoselection)
IUPAC	*Pure. Appl. Chem.* **1976**, *45*, 11.
Others	*Angew. Chem., Int. Ed. Eng.* **1966**, *5*, 385. (based on Cahn, Ingold, Prelog)
	Angew. Chem., Int. Ed. Eng. **1982**, *21*, 654. (Seebach, Prelog)
	J. Org. Chem. **1982**, *47*, 3811. (Carey, Kuehne)

2. Generalizations



1. *Z*-enolates give predominantly *syn* (or threo) aldol products (thermodynamic enolates).
2. *E*-enolates give predominantly *anti* (or erythro) aldol products (kinetic enolates).

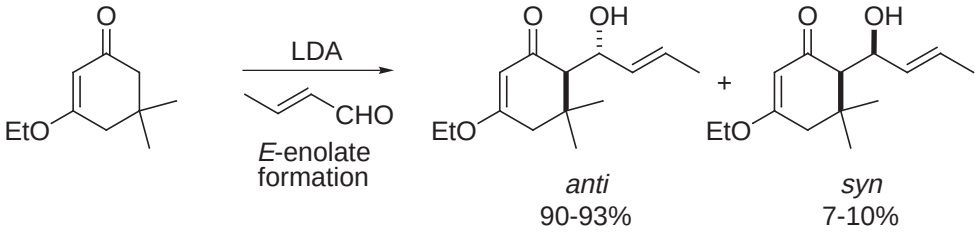
and

3. Diastereoselectivity (for *syn* aldol) of *Z*-enolates is greater than that of *E*-enolates (for *anti*).
4. Correlation for *E* or *Z*-enolate is greater when R^1 is sterically demanding.
5. Correlation is stronger when R^3 is large (most important for boron enolates).
6. Correlation is reversed when R^2 is sterically demanding (very large).

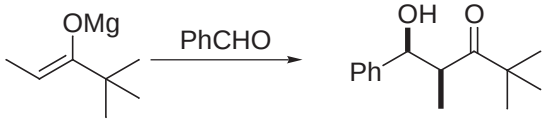
- Advances in ^{1}H NMR, ^{13}C NMR permitted detection, quantification and identification.
- Issue of equilibration addressed.

R. R. Ernst received the 1991 Nobel Prize in Chemistry for the development of the methodology of high resolution NMR spectroscopy.

3. Examples



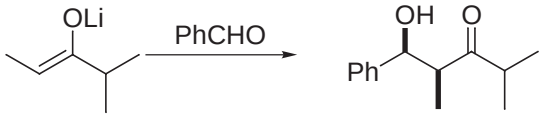
- Steric size of R^1 affects diastereoselectivity



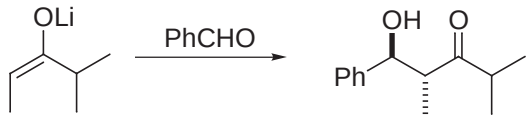
syn:*anti* >98:2

note: R^1 = ^{t}Bu > ^{i}Pr

- *Z*-enolate

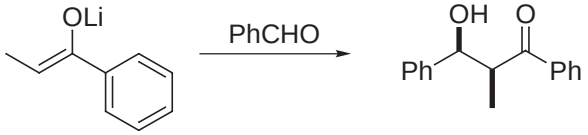


syn:*anti* 90:10



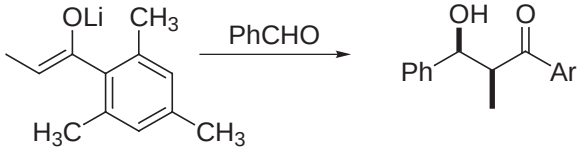
syn:*anti* 45:55

note: *Z* > *E*, stereoselectivity much lower with *E*-enolate



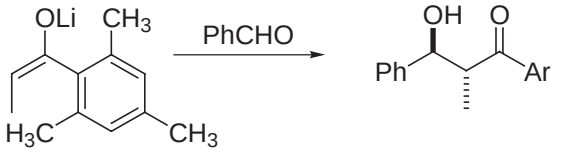
syn:*anti* 88:12

> 98:2 *Z*:*E*



syn:*anti* 88:12

87:13 *Z*:*E*



anti:*syn* 92:8

92:8 *E*:*Z*

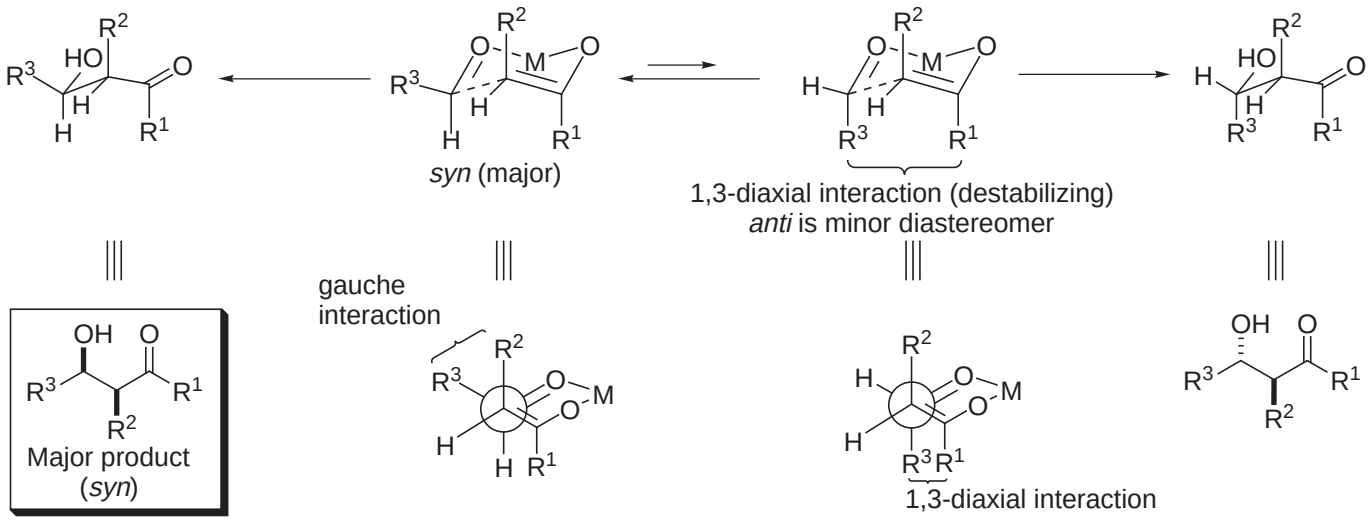
note: larger R^1 helps maintain high selectivity dictated by enolate geometry and substantially enhances *E*-enolate diastereoselectivity

Heathcock *J. Org. Chem.* **1980**, *45*, 1066.

4. Origin of Diastereoselectivity

- Zimmerman-Traxler Model (*J. Am. Chem. Soc.* **1957**, *79*, 1920)
- Chair-like, closed transition state: metal coordination to both carbonyls

a. *Z*-enolates

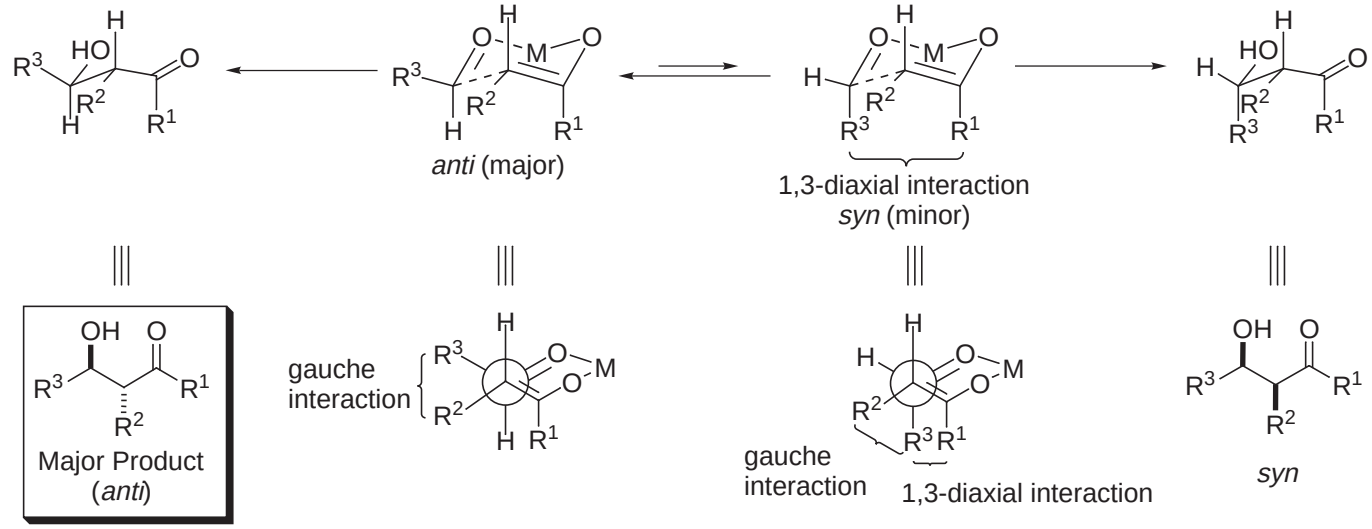


1. Diastereoselectivity for Z-enolate (giving *syn* aldol product) is maximized when R^1 and R^3 are sterically demanding (R^1/R^3 interaction is maximized).
2. Diastereoselectivity also increases as metal is changed to boron. This is attritubted to a tighter T.S. (B–O bond shorter, so R^1/R^3 steric interactions are magnified in T.S. for *anti* product).
3. When R^2 is very large the R^3/R^2 gauche interaction > R^1/R^3 1,3-diaxial interaction (Why?).

Li–O	1.92–2.00 Å
Mg–O	2.01–2.03 Å
Zn–O	1.92–2.16 Å
Al–O	1.92 Å
B–O	**1.36–1.47 Å**
Ti–O	1.62–1.73 Å
Zr–O	2.15 Å

⇐ Diastereoselection: B > Li > Na > K

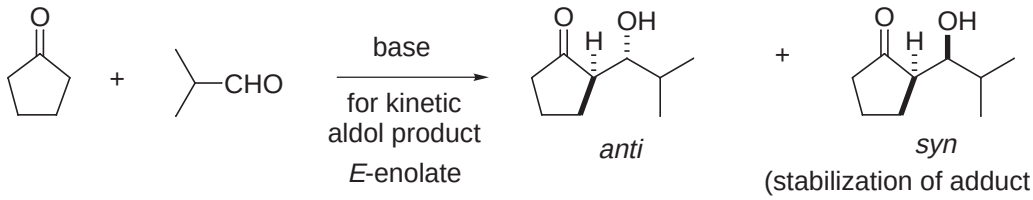
b. *E*-enolates



1. Diastereoselectivity increases as R^1 and R^3 become sterically large, and a switch to the boron enolate will increase selectivity.
2. Diastereoselectivity may switch when R^2 is very large (Why?).

5. Cyclic Ketones

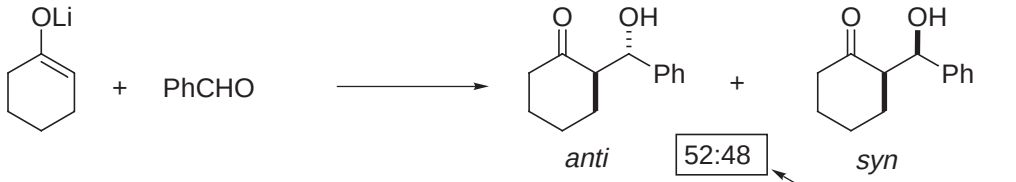
- Only *E*-enolate and therefore *anti* aldol.
- Aldol addition is reversible, can get very different stereoselectivity by allowing reaction products to equilibrate (and equilibration can be very fast).



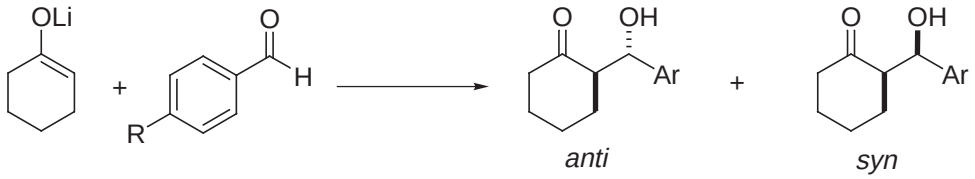
Dubois:

base	*anti*:*syn*	
LiOH	>95:5	
KOH	>95:5	
$Me_4N^+OH^-$	30:70	← thermodynamic ratio

- Instructive examples: Majewski *Tetrahedron Lett.* **1989**, *30*, 5681.
House *J. Am. Chem. Soc.* **1973**, *95*, 3310.
Heathcock *J. Org. Chem.* **1980**, *45*, 1066.



- but really is the result of equilibration: *Tetrahedron Lett.* **1989**, *30*, 5681.



THF > DME

R = H	THF	84	:	16	75%
	DME	72	:	28	50%

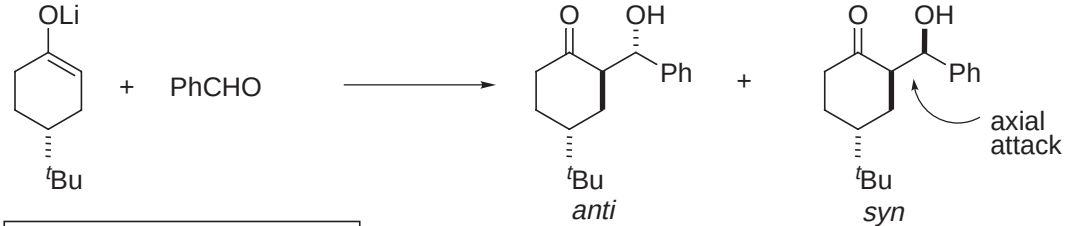
R = Ph	THF	94	:	6	67%
R = CF_3	THF	74	:	26	80%



1. *E*-enolate -> *anti* aldol.
2. Axial attack of enolate (stereoelectronic control).

THF	81	:	19	63%
Et_2O	75	:	25	61%
Et_2O-HMPA	68	:	32	68%

6. Acyclic Enolates

- Effect of R^1

	***syn* : *anti* ratio**	
R^1	*Z*-enolate	*E*-enolate
OMe	-	1.5
O^{t}Bu	-	1.0
H	1.0	1.5
Et	9.0	1.5
^{i}Pr	9.0	1.0
Ph	7	-
^{t}Bu	70	-
mesityl	>50	<0.02

typically:
Z > *E* diastereoselection

diastereoselection increases as size of R^1 increases

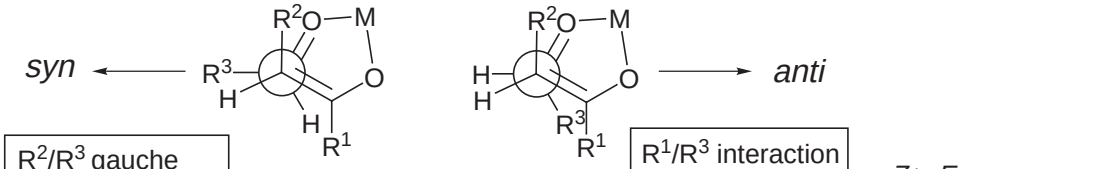
7. Refined and Alternative Models

- Idealized closed, chair transition state does not account for *Z* > *E* diastereoselectivity nor does it explain the switch in diastereoselectivity when R^2 is sterically demanding.

- Transition state for addition more closely resembles eclipsed conformation.

- Dubois, Fellmann *Tetrahedron Lett.* **1975**, 1225; *Tetrahedron* **1978**, *34*, 1349.
- Heathcock *J. Org. Chem.* **1980**, *45*, 1066.

- For *Z*-enolate

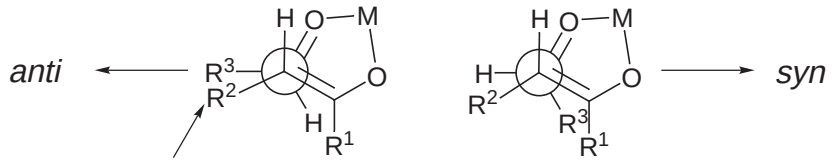


R^2/R^3 gauche interaction is further minimized

R^1/R^3 interaction even worse than in staggered

⇒ *Z* > *E* diastereoselectivity

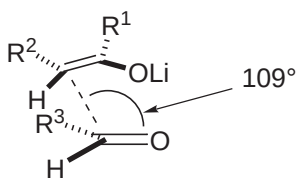
- For *E*-enolate



nearly eclipsed
much worse than gauche interaction
As R^2 increases in size, R^2/R^3 interaction competes with or surpasses R^1/R^3 interaction

⟹ *E* < *Z* diastereoselectivity
diastereoselectivity reverses when R^2 becomes sterically demanding

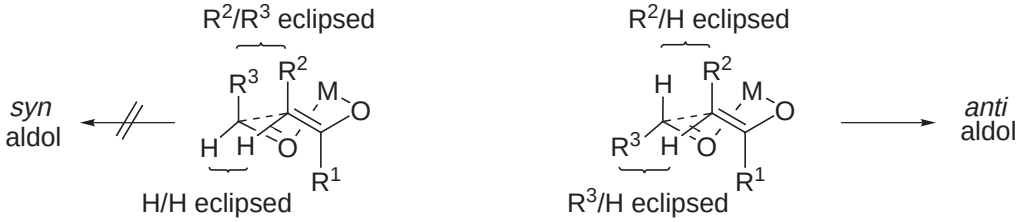
- Burgi-Dunitz approach angle -skewed approach - R^2/R^3 come closer together than R^1/R^3



- An additional alternative explanation considers the boat transition states
  Evans *Top. Stereochem.* **1982**, *13*, 1.

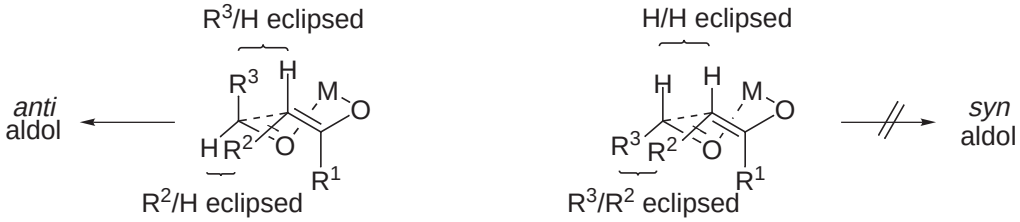
- In addition to the four idealized closed chair transition states, four closed boat transition states must be considered as well.

- *Z*-enolate



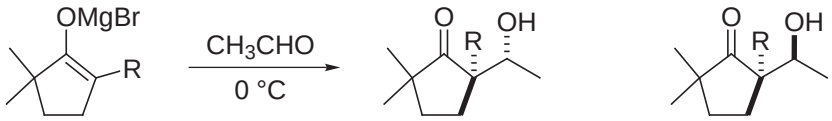
- when the R^2/R^3 gauche interaction is large in chair TS, *Z*-enolate boat TS might become competitive leading to the *anti* aldol

- *E*-enolate



- However, the boat transition state alternative does not explain the *E*-enolate switch from *anti* to *syn* aldol when R^2 becomes sterically more demanding.

- Examples



E-enolate

Dubois, Fellmann *C. R. Hebd. Seances Acad. Sci. Ser. C.* **1972**, *274*, 1307.

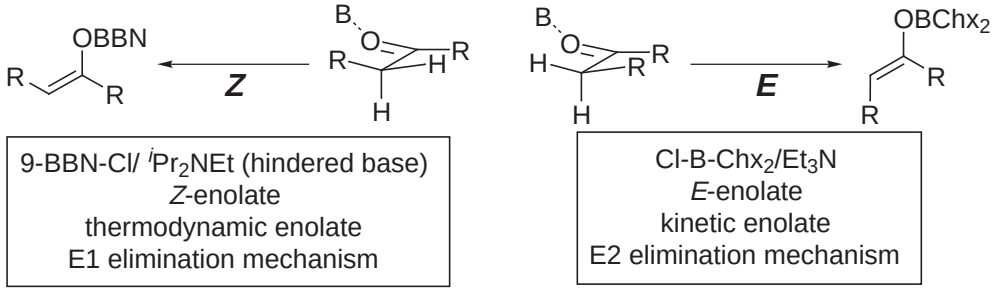
Masamune *Tetrahedron Lett.* **1979**, 2225. *E*-enolate

Bu_2BOTf, 0 °C	>95:5	10:90 *syn*/*anti*
	>95:5	5:95 *syn*/*anti*

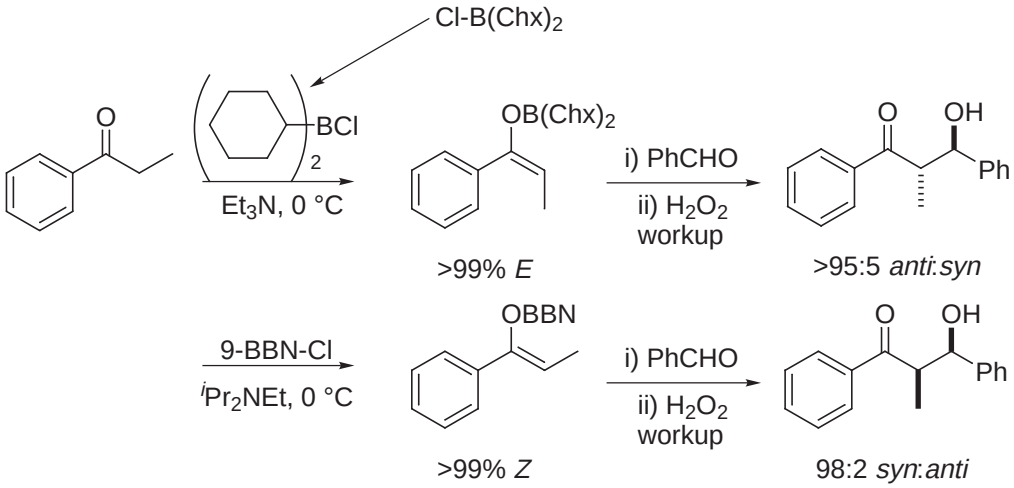
E-enolates very accessible using *t*butylthiol esters

c. Examples of more recent methods to control boron enolate geometry



9-BBN-Cl/ $^i Pr_2NEt$ (hindered base)
Z-enolate
thermodynamic enolate
E1 elimination mechanism

Cl-B-Chx_2/Et_3N
E-enolate
kinetic enolate
E2 elimination mechanism



-These results are difficult to achieve with boron triflates

Brown *J. Am. Chem. Soc.* **1989**, *111*, 3441.

- Examples

	9-BBN-Cl		99:1 (*Z*:*E*)	<1:99 (*Z*:*E*)
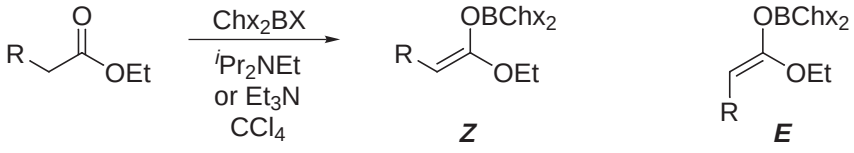
	>99:1	15:85
	98:2 (via equilibration)	<1:99
	96:4 (via equilibration)	<1:99
	99:1 (via equilibration)	21:79

Z-enolate is easy to access: thermodynamic enolate
E-enolate is less stable, more difficult to generate without equilibration
(also still difficult to prepare unless alkyl groups are bulky).

- see also Brown *J. Org. Chem.* **1992**, *57*, 499 and 2716.

Brown *J. Org. Chem.* **1994**, *59*, 2336.



Z ***E***

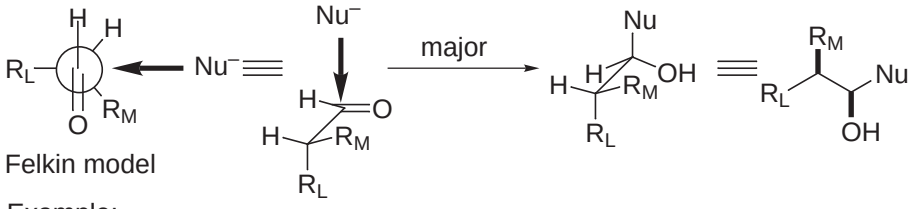
9. Aldol Condensation with Chiral Aldehydes

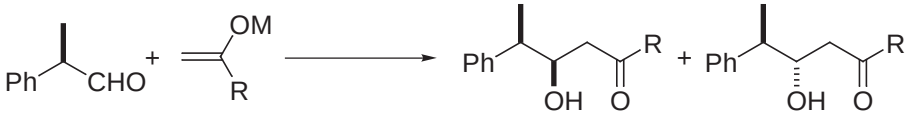
a. Felkin Addition

- Two faces of aldehyde are diastereotopic.
- Nucleophilic addition of enolate follows Cram's empirical generalization (Felkin-Ahn addition).



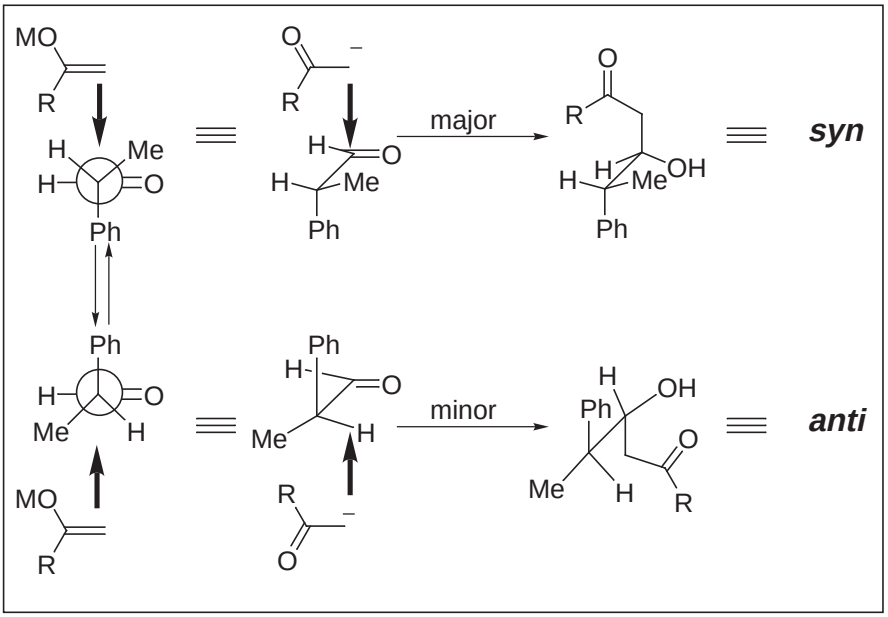
Felkin model

- Example:

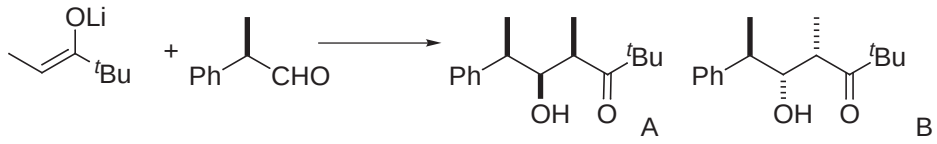


invariant diastereoselectivity with different size of R

syn 3 : *anti* 1



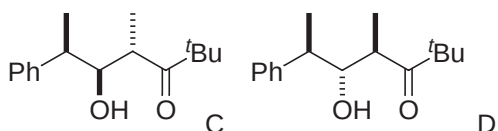
- Can combine all selectivities to give 3 contiguous chiral centers, if the chiral aldehyde and enolate partners are both highly diastereoselective.



A B

- A & B represent 2,3 *syn* products (from *Z*-enolate with large R group)

- A & C represent 3,4 *syn* products (from Cram/ Felkin-Ahn addition to aldehyde)



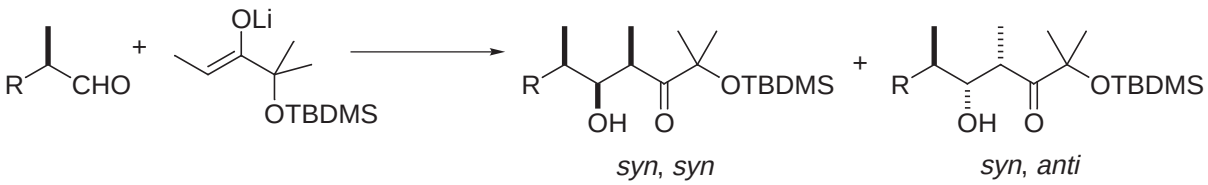
C D

experimental: A:B:C:D = 86:14:0:0

Heathcock *J. Org. Chem.* **1980**, *45*, 1066.

- *syn* aldol reaction proceeds with >98% *syn* selectivity
- Cram/Felkin-Ahn addition proceeds with 86:14 *syn* selectivity

b. Chelation Control



syn, *syn* *syn*, *anti*

R = Ph 81 : 19

Z-enolate (with large R group) gives clean *syn* aldol product for both.

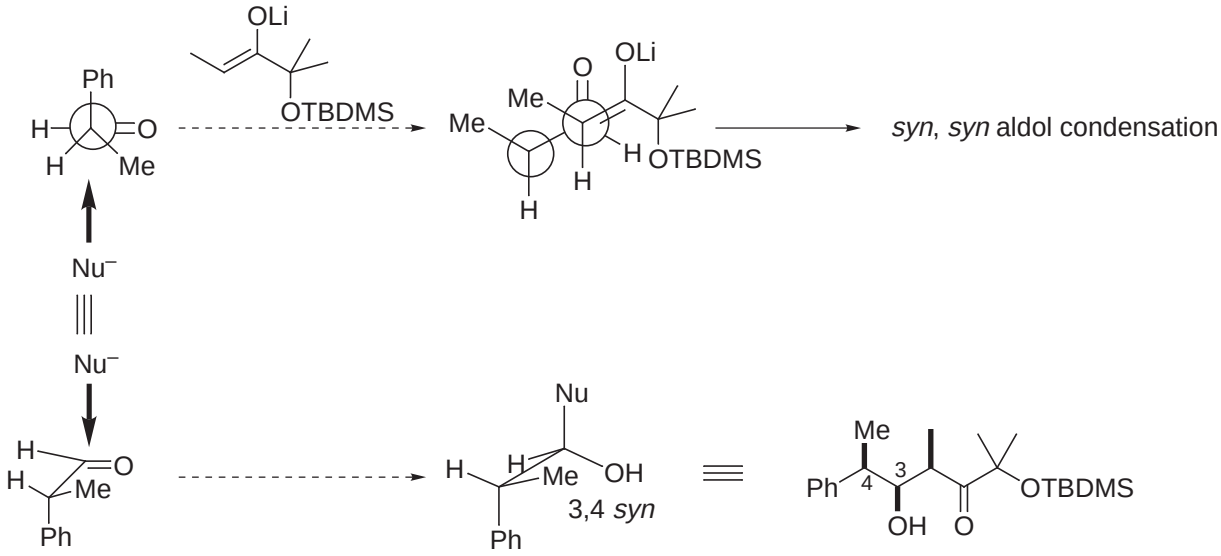
>98% *syn* aldol, 81:19 Cram addition

R = $CH_2OTBDMS$ 21 : 79

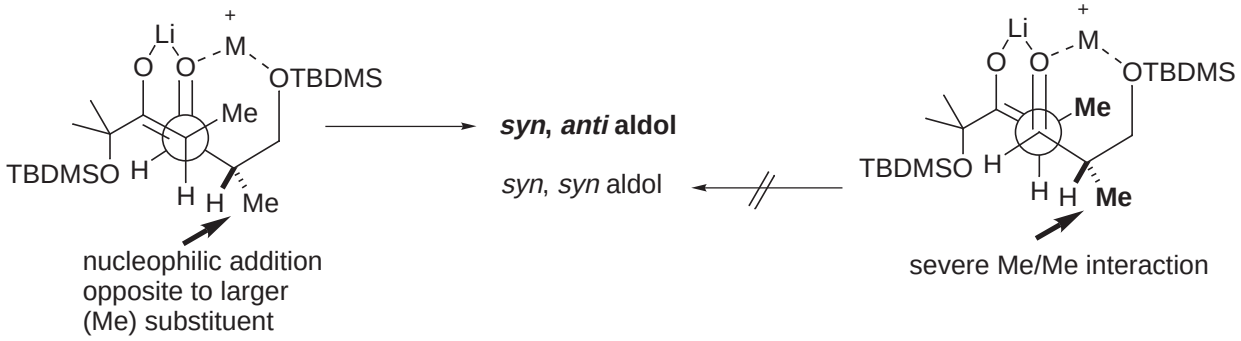
>98% *syn* aldol, 79:21 chelation-controlled addition to RCHO

Explanation of Chelation Control

1. without chelation control



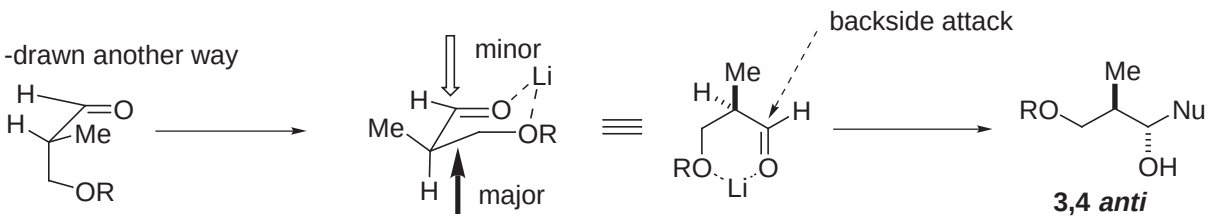
2. with chelation control



nucleophilic addition opposite to larger (Me) substituent

severe Me/Me interaction

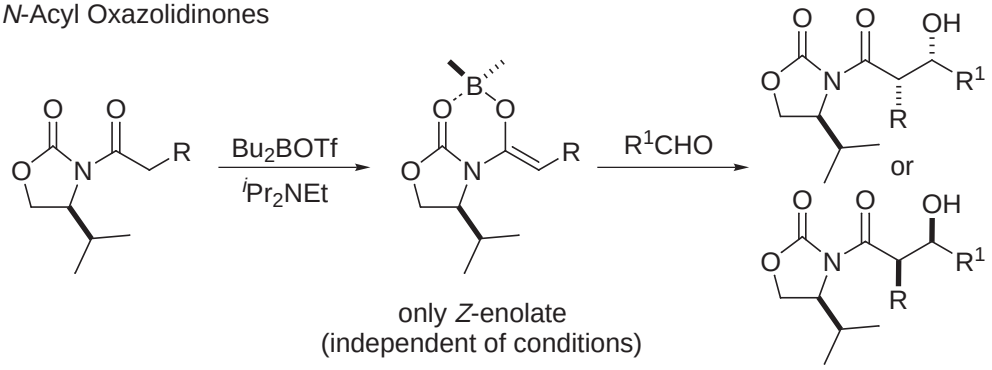
-drawn another way



3,4 *anti*

10. Aldol Condensation with Chiral Enolates

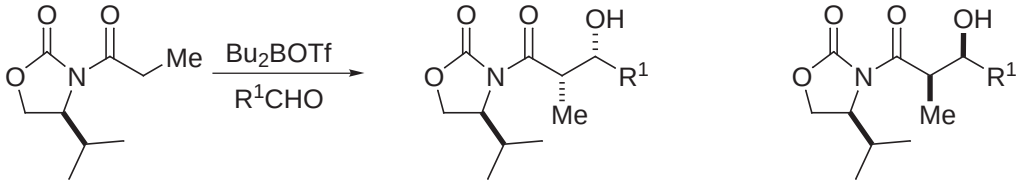
Evans' Chiral *N*-Acyl Oxazolidinones



only *Z*-enolate
(independent of conditions)

two possible *syn* aldol products
(relative to chiral center on aux.)

1. Experimental results



R^1 = ^{n}Bu	99.3	:	0.7
R^1 = ^{i}Pr	99.8	:	0.2
R^1 = Ph	>99.8	:	<0.2

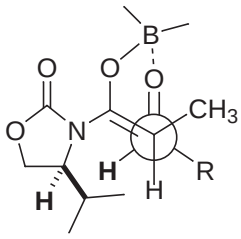
* no *anti* adducts

Evans *J. Am. Chem. Soc.* **1981**, *103*, 2876 and 3099.

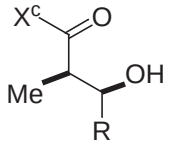
2. Origin of diastereoselectivity

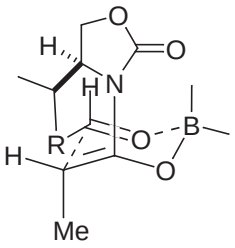
- *Z*-enolate (boron-enolate/amide) gives *syn* aldol

Chair transition state
non-chelated *Z*-enolate



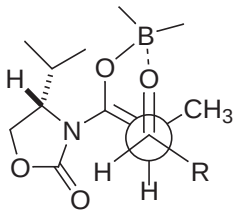
(minor *syn* aldol product)



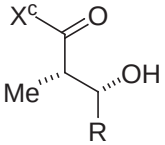


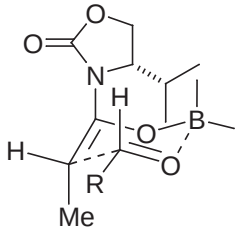
- H-H interaction
- steric interaction with ^{i}Pr (facial selectivity)
- aligned dipoles less favorable

Aldehyde R group equatorial
(axial would give *anti* aldol)



observed *syn* aldol product

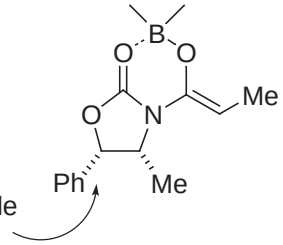




- chiral auxiliary rotates
- non-chelated enolate:
  opens coordination site on
  boron required to complex and activate aldehyde

3. For the alternative enantiomer

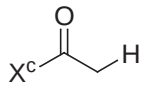
Auxiliary with the opposite absolute configuration or the more accessible



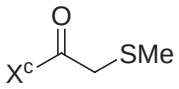
RCHO

	syn				*anti*		
R = ^{n}Bu	>99.8	:	<0.2	:	0	:	0
R = ^{i}Pr	>99.8	:	<0.2	:	0	:	0
R = Ph	>99.8	:	<0.2	:	0	:	0

- Note: selectivity not good for

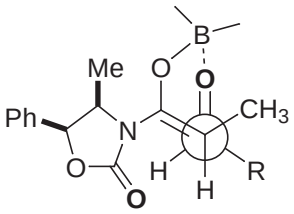


- Solution: use removable substituent

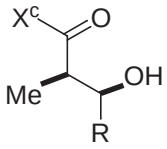


Evans aldol overrides any chiral aldehyde directing preference: *i.e.* Felkin-Ahn preference.

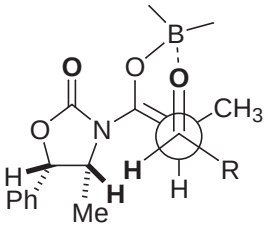
As before - two possible transition states for *syn* aldol product formation



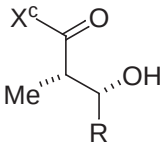
- *anti* carbonyl conformation



observed *syn* aldol product



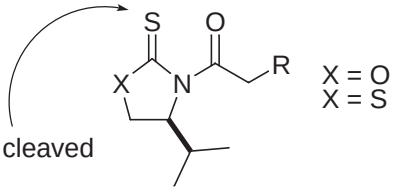
- *syn* carbonyl conformation
- steric interactions between H's



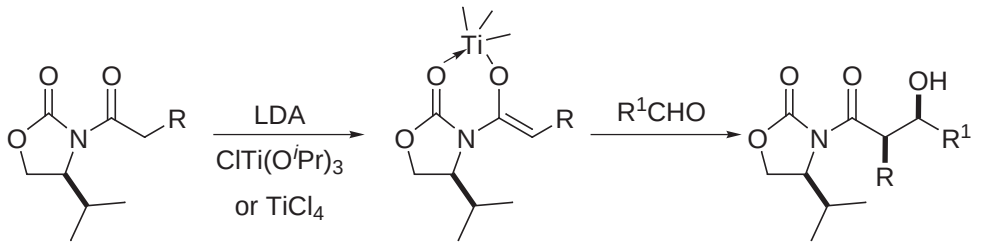
(minor *syn* aldol product)

Note: Availability of oxazolidinone alternatives
Fujita *J. Org. Chem.* **1986**, *51*, 2391.
Crimmins *J. Am. Chem. Soc.* **1997**, *119*, 7883.

Advantages: S > O for chelation and more readily cleaved



4. Ti enolate promoted Evans aldol (non-Evans *syn* aldol)



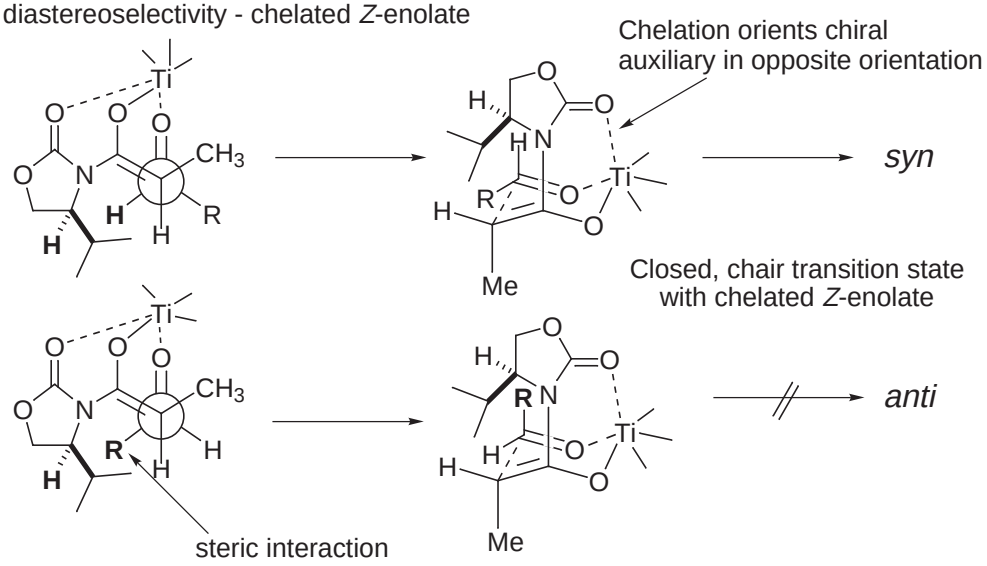
Et_2O vs. THF as solvent

Z-enolate and chelated enolate higher coordination sphere of Ti

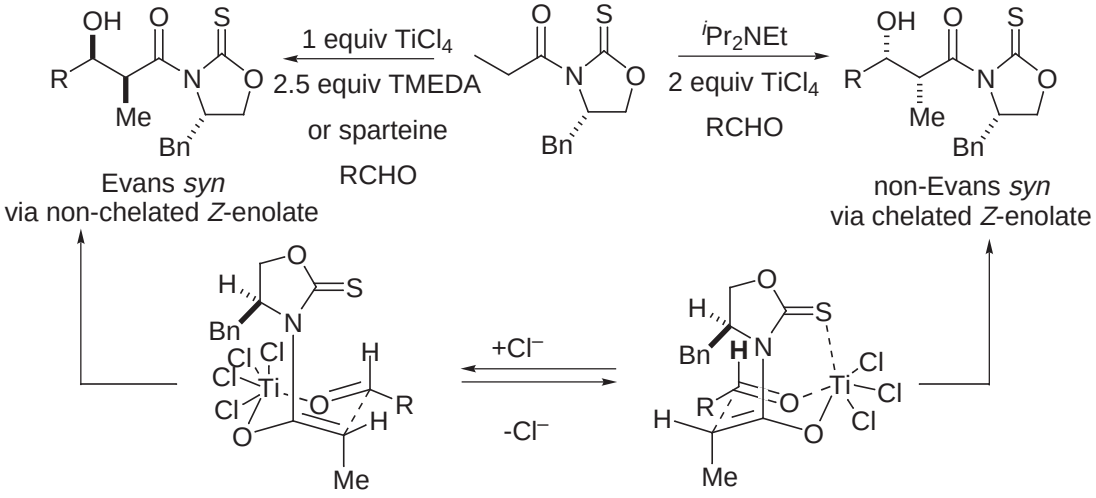
Thornton *J. Am. Chem. Soc.* **1989**, *111*, 5722; **1991**, *113*, 1299.
Evans *J. Am. Chem. Soc.* **1991**, *113*, 1047.
Thornton *J. Org. Chem*. **1991**, *56*, 2489.

syn aldol product but opposite absolute stereochemistry (non-Evans *syn* aldol).

5. Origin of diastereoselectivity - chelated *Z*-enolate



6. Chelated and non-chelated Ti enolates



Crimmins *J. Am. Chem. Soc.* **1997**, *119*, 7883.

7. Anti-selective additions

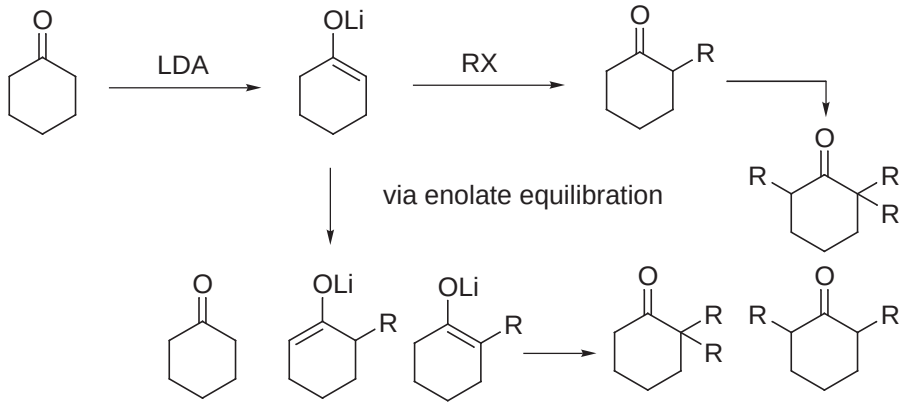
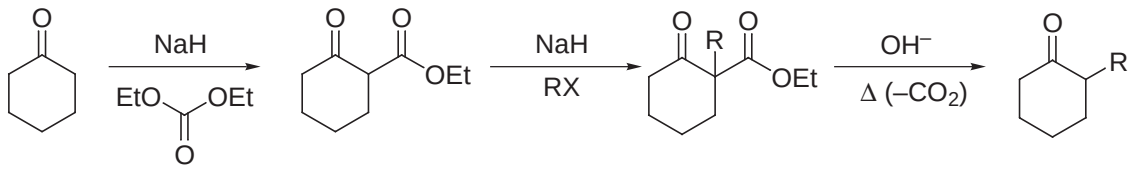
M. Metalloimines, Enamines and Related Enolate Equivalents

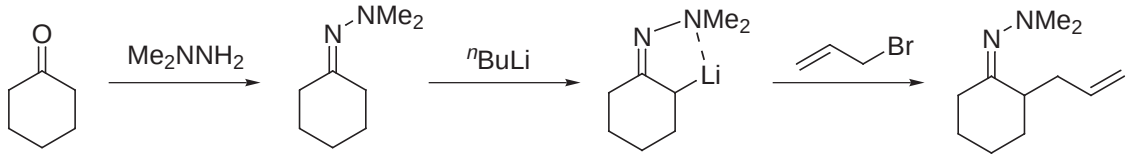
- Corey, Enders *Tetrahedron Lett.* **1976**, 3.
  (Dimethylhydrazones)



- Simple alkylation of enolates not always straightforward.
- Can get polyalkylation mixtures.

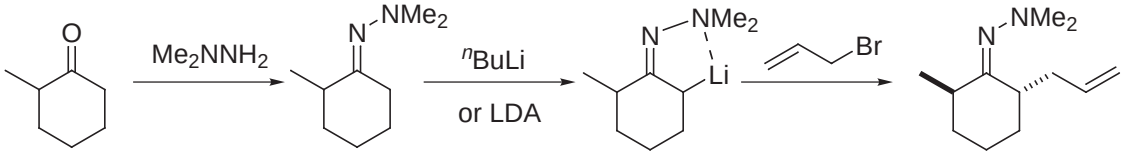
- Solutions



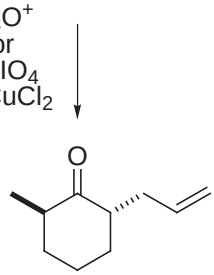


pK_a = 20 pK_a = 30

- Higher p*K*a so anion is more reactive
- Alkylation much faster and polyalkylation is not a problem

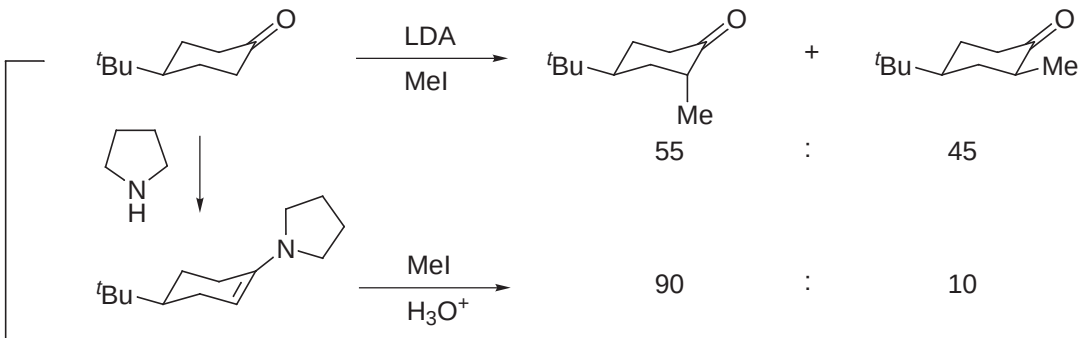


pK_a = 20 pK_a = 30

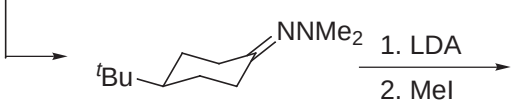


Advantages:
- monoalkylation (more reactive than ketone enolate).
- no enolate anion equilibration.
- regioselective (deprotonation at least substituted site).
- alkylation is in axial mode (diastereoselective).

- Examples:

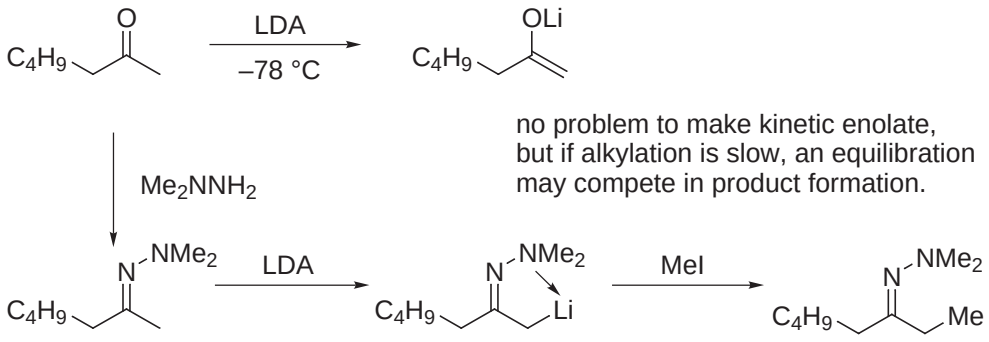


Stork enamine (*J. Am. Chem. Soc.* **1963**, *85*, 207)

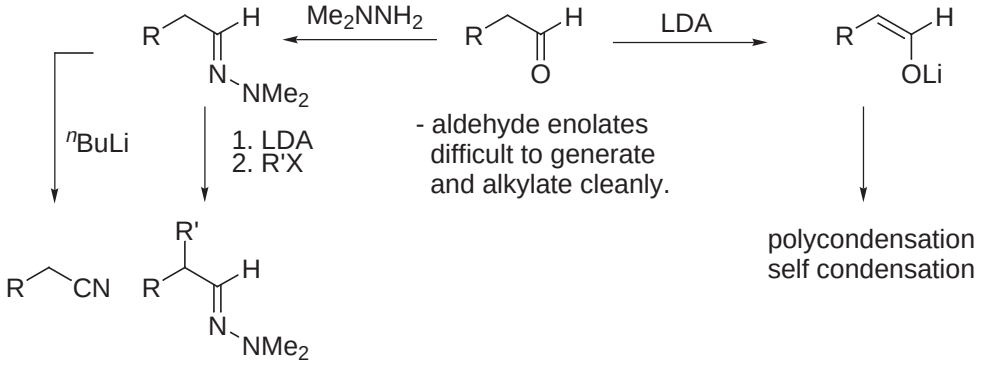


Corey dimethylhydrazone

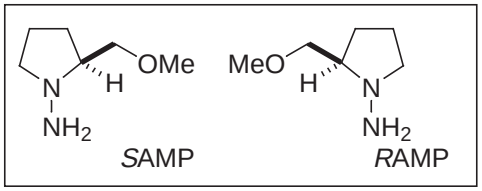
-also useful in acyclic cases



- very good as aldehyde enolate equivalents



- Enders chiral hydrazones (*S*AMP and *R*AMP)



- alkylation from the
least hindered face
of chelated anion.

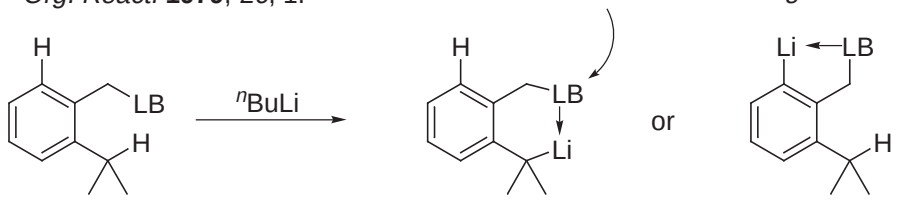
IX. Metalation Reactions

A. Directed Metalation

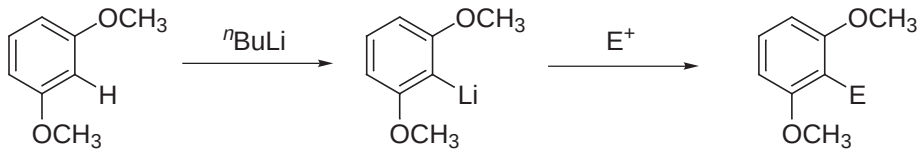
- Kinetic acceleration of deprotonation of a relatively non-acidic site.
- *Synthesis* **1983**, 95.
- *Acc. Chem. Res.* **1982**, *15*, 306.
- *Org. React.* **1979**, *26*, 1.

lateral lithiation: *Org. React.* **1995**, *47*, 1.

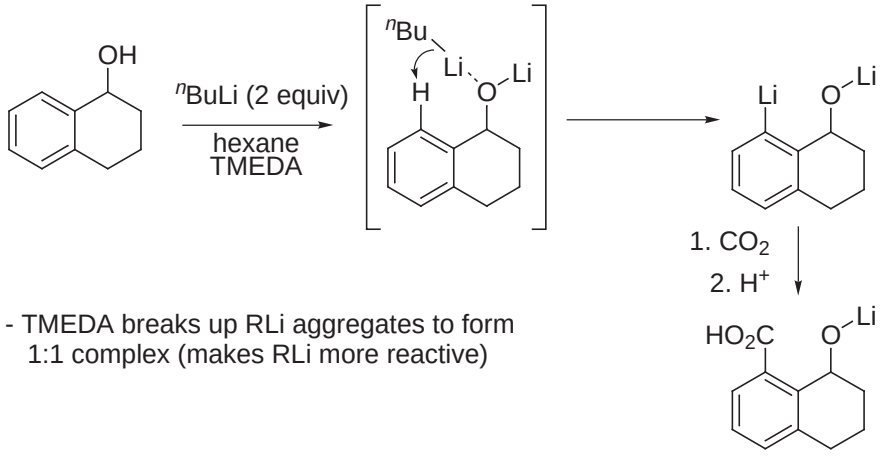


- Usually requires very strong base (^{n}BuLi, ^{s}BuLi or ^{t}BuLi, sometimes LDA).
- Sometimes requires additives (TMEDA, DABCO) to break up Li aggregates (make bases more reactive).

- Examples:

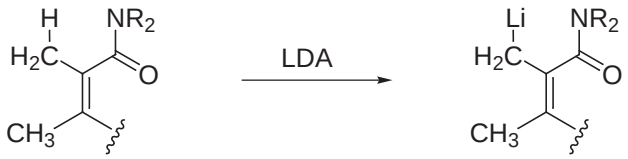


- All aromatic H's have approximately the same pK_a



- TMEDA breaks up RLi aggregates to form 1:1 complex (makes RLi more reactive)

- Not limited to aromatic substrates



- Kinetic acceleration of deprotonation even in the presence of a more acidic proton.

- Directed Metalation Groups

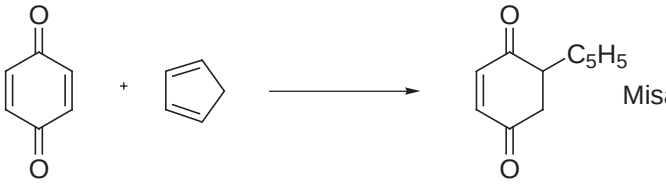
2. Discovery

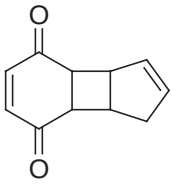
Wieland (*Ber*. **1906**, *39*, 1492) described the 1:1 dimerization of conjugated dienes in what was probably the first report of a Diels-Alder reaction.

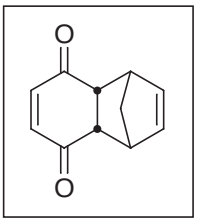
Albrecht (Thiele) Reaction:
Ann. **1906**, *348*, 31.



Misassigned structure

Staudinger Structure:
Die Ketene, Stuttgart
1912, 59.

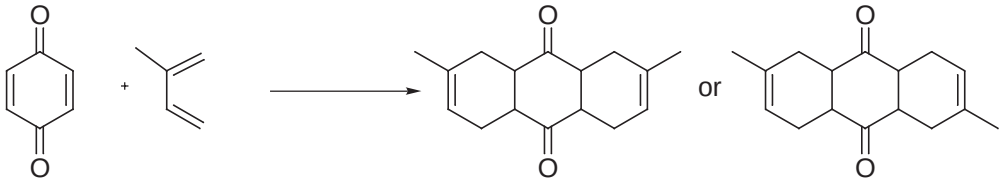




Structure established by Diels and Alder, and they went on to define scope and mechanism of the reaction. For this, they received the 1950 Nobel Prize in Chemistry.

Diels and Alder *Ann*. **1928**, *460*, 98.

In fact, von Euler had correctly, but tentatively, identified the 2:1 adduct of isoprene with *p*-benzoquinone before Diels and Alder's work. von Euler, Josephson *Ber*. **1920**, *53*, 822.



von Euler received the 1929 Nobel Prize in Chemistry for his investigations on fermentations of sugars and the fermentative enzymes. He had trained with Landolt, Nernst, van't Hoff, Arrhenius, Hantzsch, and Thiele and was remarkable in his scientific pursuits. By 1910, he had already initiated his monumental studies of enzyme structure, kinetics, and mechanism and his occasional forays into pure organic chemistry were just as remarkable.

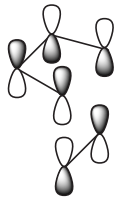
For an engaging description of the discovery of the Diels-Alder reaction, the competition for its exploration and applications, and the missed opportunities, see: Berson *Tetrahedron* **1992**, *48*, 3.

Even in their first disclosure, Diels and Alder recognized the potential the reaction might hold for synthesis: "Thus, it appears to us that the possibility of synthesis of complex compounds related to or identical with natural products such as terpenes, sesquiterpenes, perhaps also alkaloids, has moved to a near prospect." They also felt this could be reserved: "We explicitly reserve for ourselves the application of the reaction discovered by us to the solution of such problems." Fortunately, their claims were ignored and an extraordinary group of investigators helped define the scope and mechanism of the Diels-Alder reaction.

The first applications in total synthesis include: Cortisone by Woodward, Sondheimer *J. Am. Chem. Soc.* **1951**, *73*, 2403; Sarett (Merck) *J. Am. Chem. Soc.* **1952**, *74*, 4974. Cantharidin by Stork, Burgstahler, van Tamelen *J. Am. Chem. Soc.* **1951**, *73*, 4501.

3. Mechanism, FMO Treatment

$[\pi^2s + \pi^4s]$ Cycloaddition

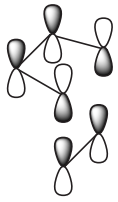


$HOMO_{diene}$

$LUMO_{dienophile}$

This is the dominant interaction in a normal Diels-Alder reaction.

Alternatively:



$LUMO_{diene}$

$HOMO_{dienophile}$

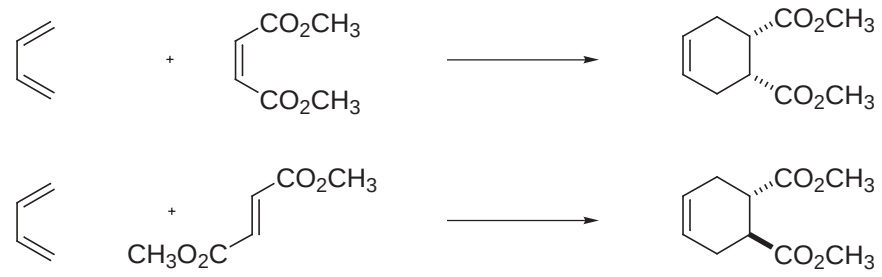
Dominant interaction in an inverse electron demand Diels-Alder reaction.

1. Large E_a for the reactions.
2. Driving force is formation of two new σ bonds accompanying the loss of two π bonds.

4. Diastereoselectivity

a. *cis* Principle: Geometry of dienophile and diene are maintained in the [4 + 2] cycloadduct.

e.g.

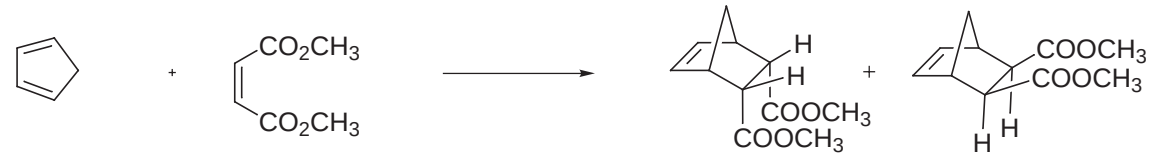


Stereospecific

b. Alder's Endo Rule:

Stereoselective ← *Endo* product and *endo* transition state predominate even though *exo* products are usually more stable; *endo* is the kinetic product.

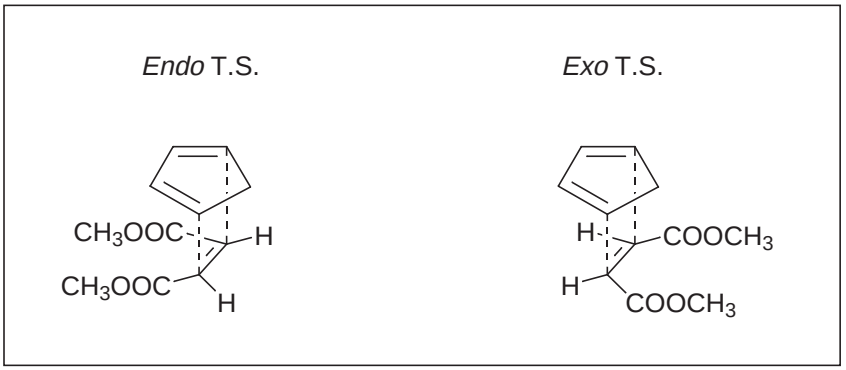
e.g.



endo Major

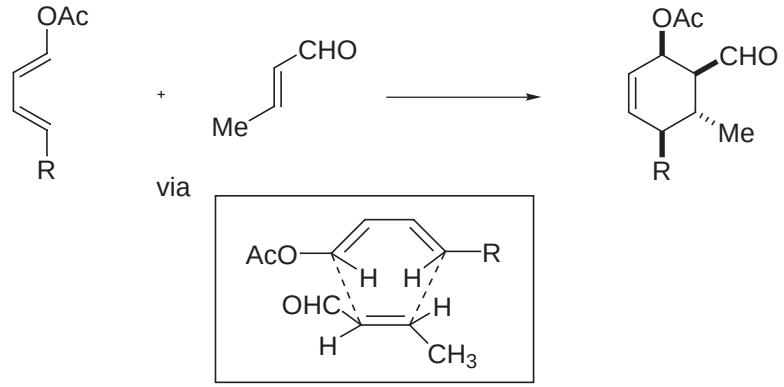
exo Minor

Endo, boat transition state



Result: Both *cis* rule and *endo* rule ⟹ Diels-Alder reaction very useful, diastereoselective

c. Factors influencing *endo* selectivity of the Diels-Alder reaction

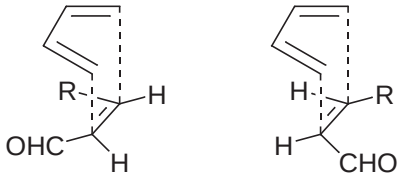


i. *Endo* transition state is favored by stabilizing secondary orbital interactions.

ii. *Endo* selectivity often increases with the use of Lewis acid catalysis.

iii. *Endo* selectivity often increases with increase in pressure of reaction.

Endo selectivity ↑ , pressure ↑ $\Delta\Delta V^{\ddagger}$ = –4 to –8 cm^3/mol (*endo*/*exo*)



endo T.S. *exo* T.S.

Raistrick *J. Chem. Soc.* **1939**. 1761, 1770.
Jones *Tetrahedron* **1962**, *18*, 267.
Dauben demonstrated pressure-promoted reactions are viable:
J. Am. Chem. Soc. **1974**, *96*, 3664.
J. Am. Chem. Soc. **1976**, *98*, 1992.
J. Org. Chem. **1977**, *42*, 282.

$-\Delta V^{\ddagger}$ is negative (–25 to –38 cm^3/mol). So increase pressure, increase rate of reaction.

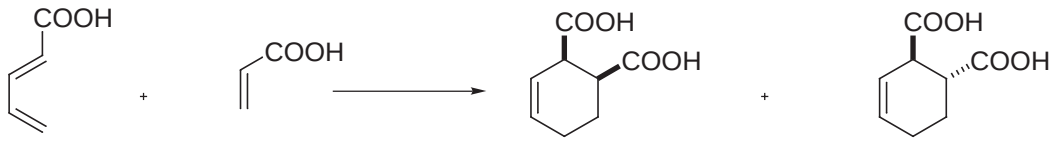
↓

-And *endo* T.S. is more compact, so $\Delta\Delta V^{\ddagger}$ for *endo*:*exo* also negative.
(i.e., diastereoselectivity increases)

Example of  Boger *J. Am. Chem. Soc.* **1988**, *108*, 6695 and 6713.

iv. *Endo* selectivity also increases with decreases in temperature at which the reaction is conducted

e.g.

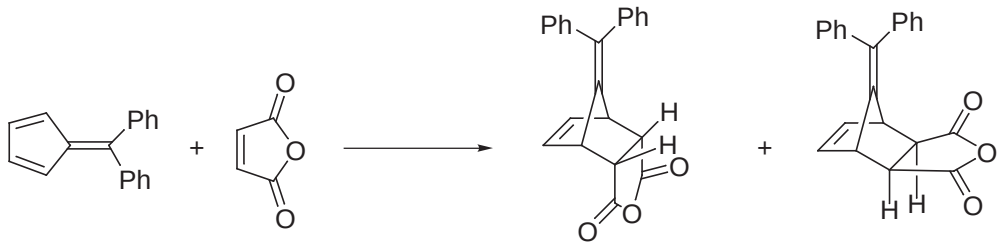


temp.	*endo*		*exo*
75 °C	only *endo*		
90 °C	7	:	1
100 °C	4.5	:	1
110 °C	2	:	1
130 °C	1	:	1

Endo selectivity ↑ , temperature ↓

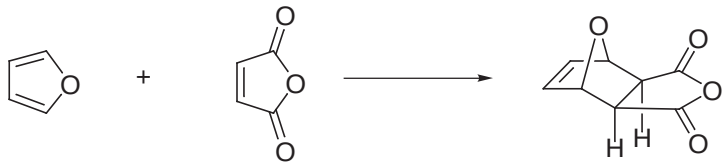
	conditions	*endo*		*exo*
	10 days, 0 °C	66	:	34
	6 h, 200 °C	34	:	66
Lewis acid-catalyzed	BF_3•OEt_2, 5 min, –20 °C	90	:	10

Furukawa *J. Am. Chem. Soc.* **1970**, *92*, 6548.



temp.	*endo*		*exo*
25 °C	100	:	0
140 °C	29	:	71

Some Diels-Alder adducts are thermally unstable (reversible) and subject to equilibration via retro Diels-Alder reaction to provide the most stable product: Ripoll *Tetrahedron* **1978**, *34*, 19.

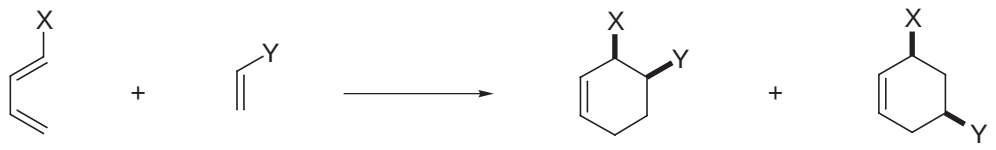


100% *exo*

see also: Rickborn *Org. React.* **1998**, *52*, 1.

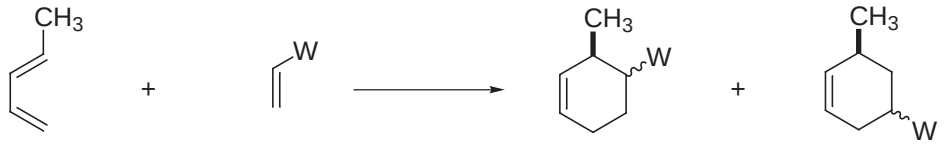
5. Regioselectivity

a. 1-Substituted dienes react with substituted dienophiles to give the *ortho* product:



usually around 9:1

For example:

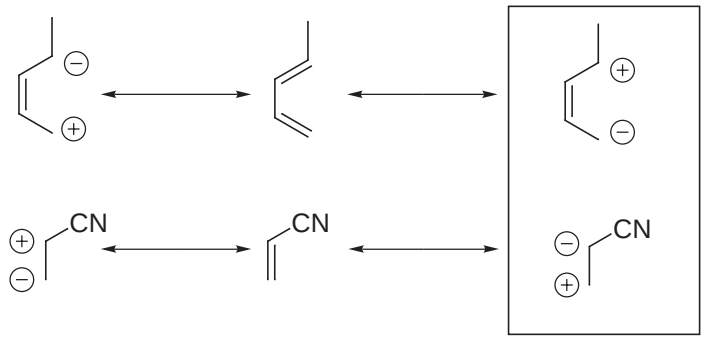


W = CN	100 °C, 12 h, 30%	9	:	1
= COOR	200 °C, 2 h, 85%	6.8	:	1

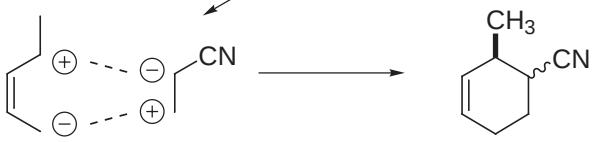
higher temperature decreases regioselectivity

regioselectivity lower, because COOR not as strongly electron-withdrawing as CN

-Device for predicting regioselectivity: draw out "zwitterionic" representations (resonance structures) for the reactants.

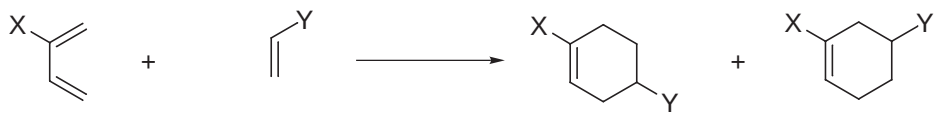


more stable resonance forms



Reaction: 100 °C, 12 h
30%, 9:1 regioselectivity

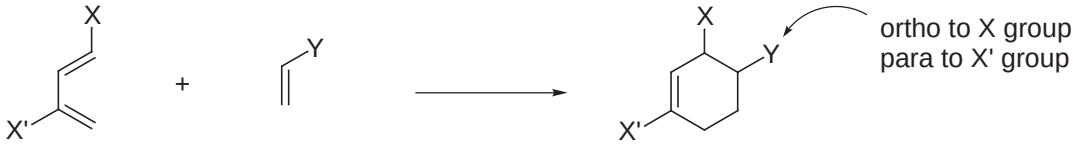
b. 2-Substituted dienes give predominantly the *para* product:



X = CH_3	Y = $COOCH_3$	6	:	1	higher regio-selectivity because OCH_3 better donating group than CH_3.
= OCH_3	= $COOCH_3$	10	:	1	
= CN	= $COOCH_3$	10	:	1	

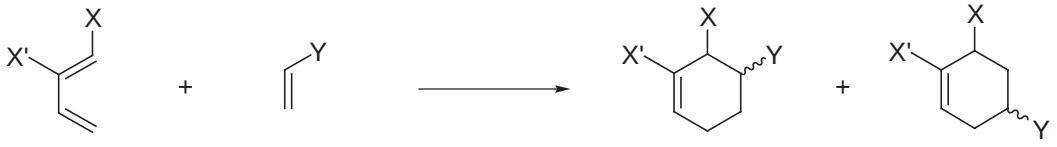
c. Complementary substitution usually provides even greater regioselectivity

-1,3-Disubstituted Dienes



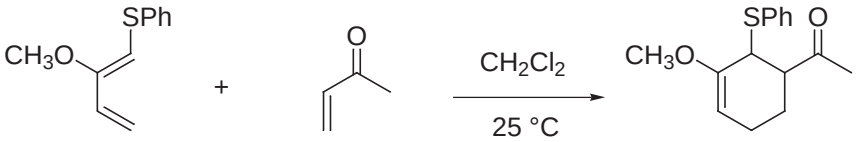
But noncomplementary substitution may cause problems (lower regioselectivity)

-1,2-Substituted Dienes



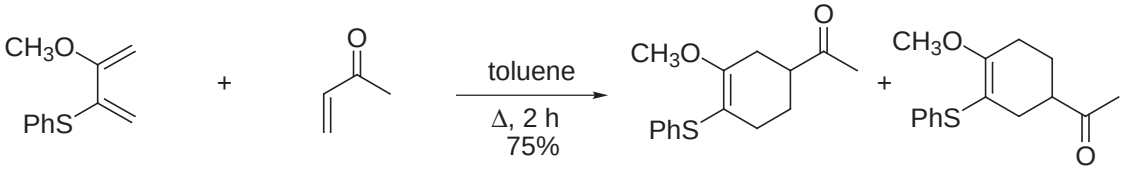
relative amounts of each depend on electron donating strength of substituents X and X'

$NHCO_2R > SR > OR > alkyl > H$



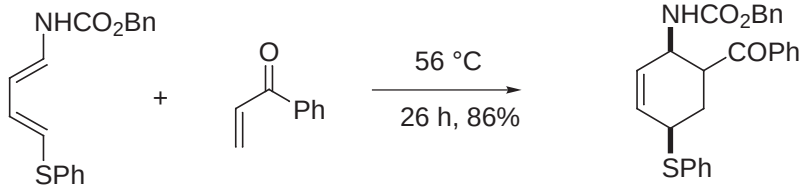
85% 100:0

Cohen *J. Org Chem*. **1982**, *47*, 4005.



> 5 : 1

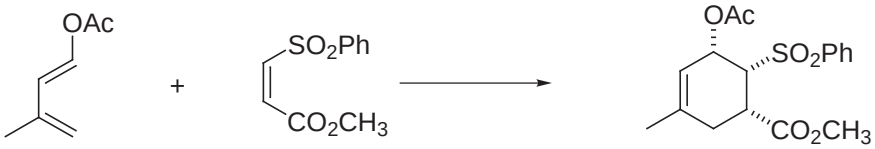
Trost *J. Am. Chem. Soc*. **1980**, *102*, 3548.



Overman *J. Am. Chem. Soc*. **1983**, *105*, 6335.

d. Apparent regioselectivity can be altered by adding a controlling group that is subsequently removed

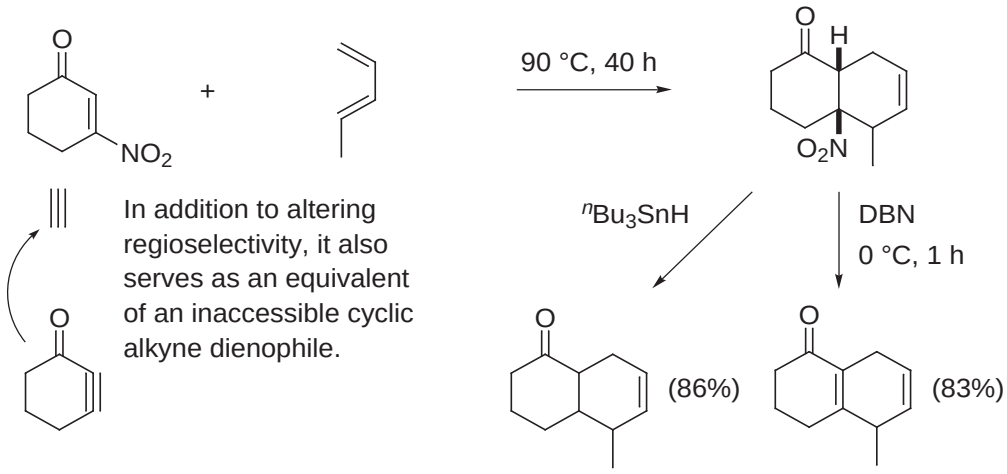
-Dienophile



-*endo* addition
$-CO_2CH_3$ is in *meta* position
$-SO_2Ph > CO_2CH_3$ in controlling regioselectivity

Bass *J. Chem. Soc., Chem. Commun.* **1987**, 1836.

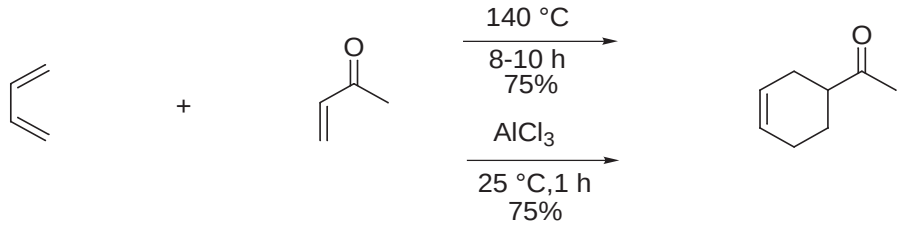
- Diene



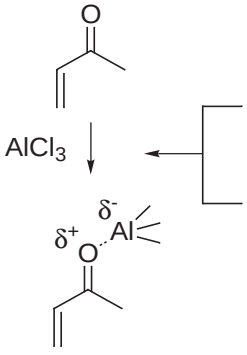
Corey *Tetrahedron Lett.* **1981**, *22*, 603.
Ono *J. Chem. Soc., Perkin Trans. 1* **1987**, 1929.
Tanis *Syn. Commun.* **1986**, *16*, 251.

Rate of reaction generally insensitive to solvent polarity, but...

6. Lewis Acid Catalysis



Addition of Lewis Acid Catalysts:



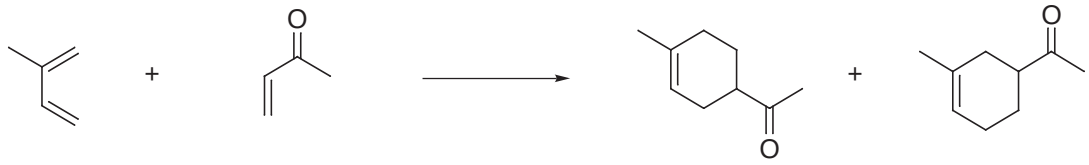
i. Lowers LUMO of dienophile, so increases rate of reaction.

ii. Increases the difference in magnitude of coefficients of dienophile
-----so increases regioselectivity.

iii. Changes coefficient at dienophile substituent, so increases opportunity of secondary orbital interactions
.....often increases *endo* stereoselectivity.

Increases: 1. Reaction Rate
2. Reaction Regioselectivity
3. Reaction *Endo* Diastereoselectivity

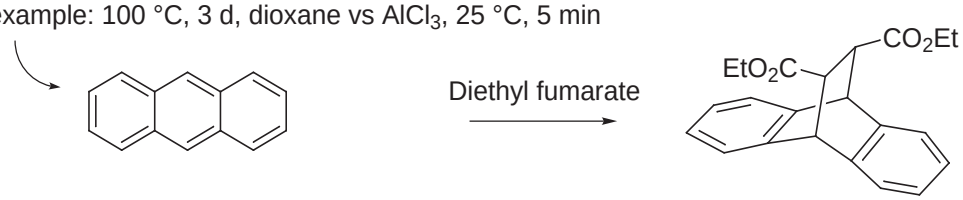
-Examples



Lutz *J. Am. Chem. Soc.* **1964**, *86*, 3899. toluene, 120 °C, 24 h 71 : 29

Yates *J. Am. Chem. Soc.* **1960**, *82*, 4436. $SnCl_4$, benzene, 25 °C, 1 h 93 : 7

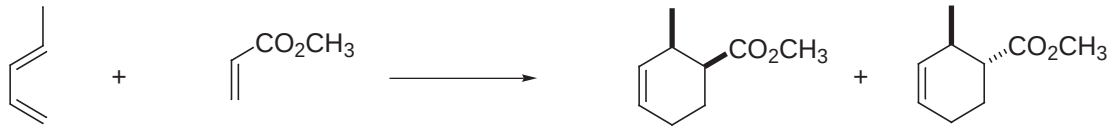
1st example: 100 °C, 3 d, dioxane vs $AlCl_3$, 25 °C, 5 min



$AlCl_3$: $\Delta G^{\ddagger}$ 9.3 kcal/mol lower than uncatalyzed reaction

Inukai, Kojima *J. Org. Chem.* **1967**, *32*, 872.

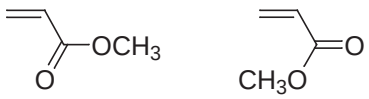
ΔE *endo/exo*:



uncat. reaction: 0.2 kcal/mol; $AlCl_3$ cat. reaction: 1.8 kcal/mol

Spellmeyer , Houk *J. Am. Chem. Soc.* **1988**, *110*, 3412.
Jensen, Houk *J. Am. Chem. Soc.* **1987**, *109*, 3139.

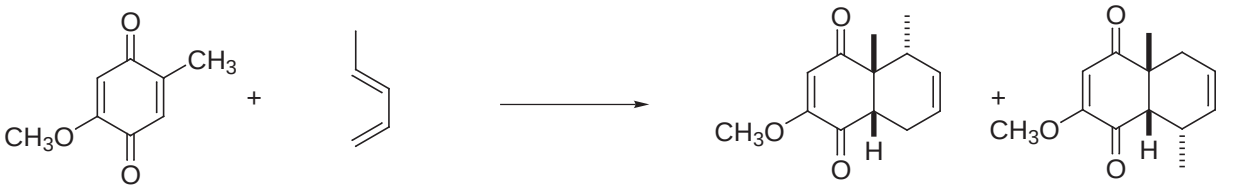
Calculations: s-*cis* > s-*trans*



ΔE for:	catalyzed reaction:	uncatalyzed reaction:
	1.9 kcal/mol for *endo*	0.6 kcal/mol for *endo*
	2.7 kcal/mol for *exo*	1.7 kcal/mol for *exo*

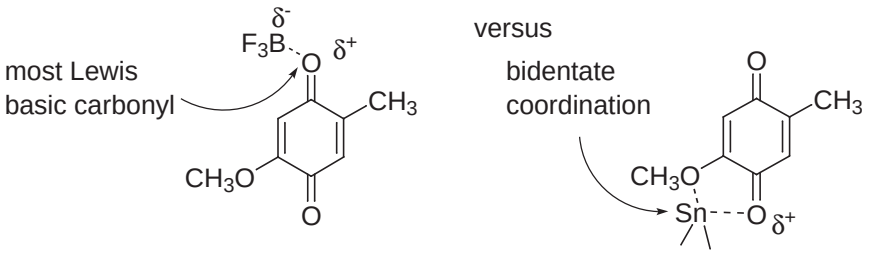
Birney, Houk *J. Am. Chem. Soc.* **1990**, *112*, 4127.

-Lewis Acid catalysis can also alter regioselectivity



100 °C	1	:	1	80%
BF_3•OEt_2, –16 °C	4	:	1	>85%
cat. $SnCl_4$, –16 °C	1	:	20	>85%

Rationalization: monodentate vs. bidentate coordination



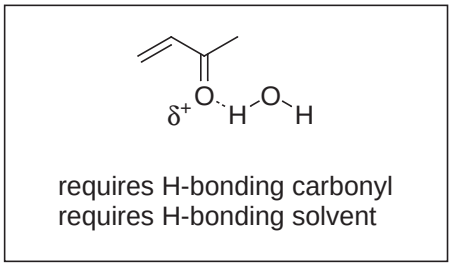
-Hydrophobic effect: H_2O solvent acceleration:

Breslow *J. Am. Chem. Soc.* **1980**, *102*, 7816.
Rideout *Tetrahedron Lett.* **1983**, *24*, 1901.

also:

Sternbach *J. Am. Chem. Soc.* **1982**, *104*, 5853.
Grieco *Tetrahedron Lett.* **1983**, *24*, 1897.

Jorgensen - Hydrogen-bonding of H_2O serves in the same capacity as a mild Lewis acid.

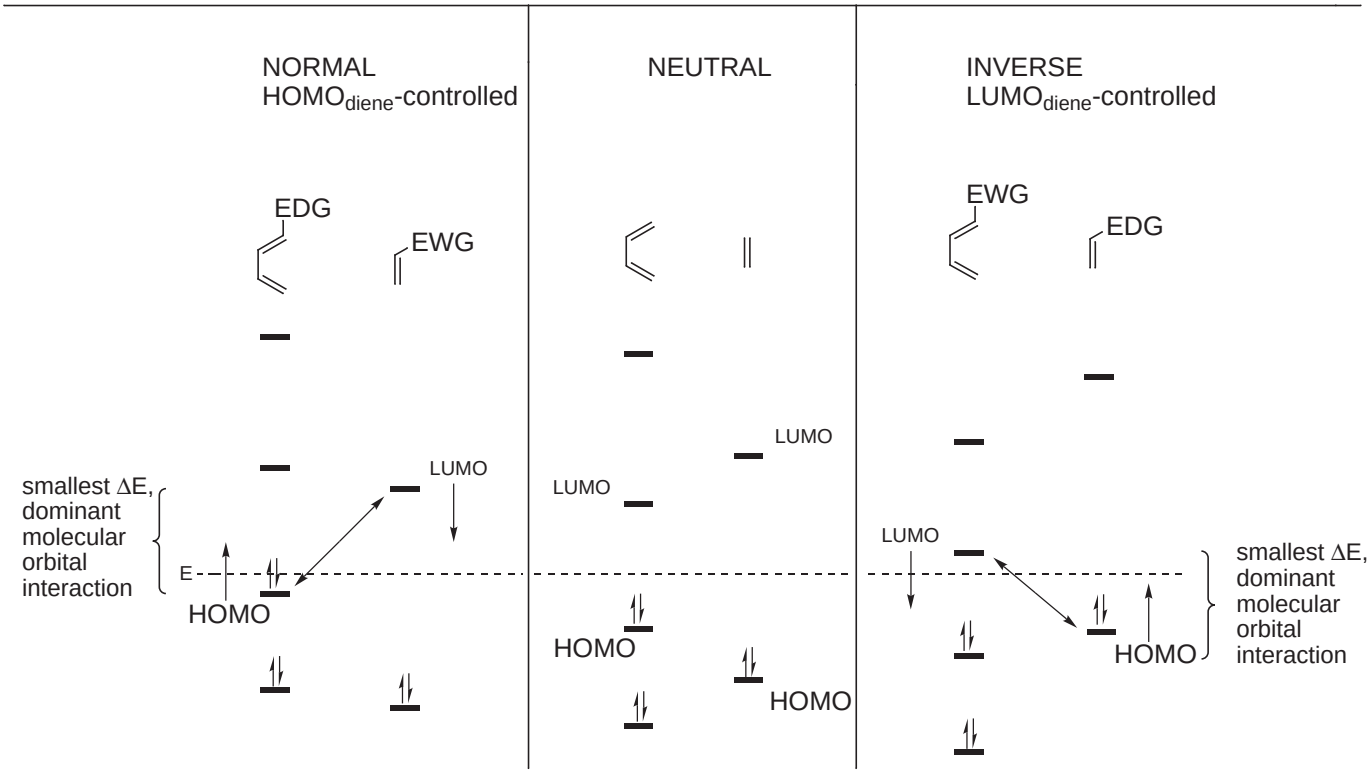


Jorgensen *J. Am. Chem. Soc.* **1991**, *113*, 7430.
J. Org. Chem. **1994**, *59*, 803.

7. Detailed FMO Analysis

-Using simple computational tools now available, one can quickly and easily predict regioselectivity and comparatively assess rate and diastereoselectivity of a Diels-Alder reaction by examining the frontier molecular orbitals (FMO). Each of the calculations that follow took < 1 min to run.

Classification of Diels-Alder Reactions.



J. A. Pople (computational methods in quantum chemistry) and W. Kohn (density-functional theory) received the 1998 Nobel Prize in Chemistry for their pioneering contributions to theoretical and computational methods for defining properties and chemical behavior.

Common Computational Tools:

Semiempirical

MNDO: Dewar *J. Am. Chem. Soc.* **1977**, *99*, 4899.

AM1: Dewar *J. Am. Chem. Soc.* **1985**, *107*, 3902.

Ab Initio

Gaussian: Pople, Carnegie-Mellon Quantum Chem. Pub. Unit, Pittsburgh, PA.

AM1 Theoretical Highest Occupied π Orbital (HOMO) and Lowest Unoccupied π Orbital (LUMO)

π system	E		Coefficients			
H_2C=CH-CH=O			O-1	C-2	C-3	C-4

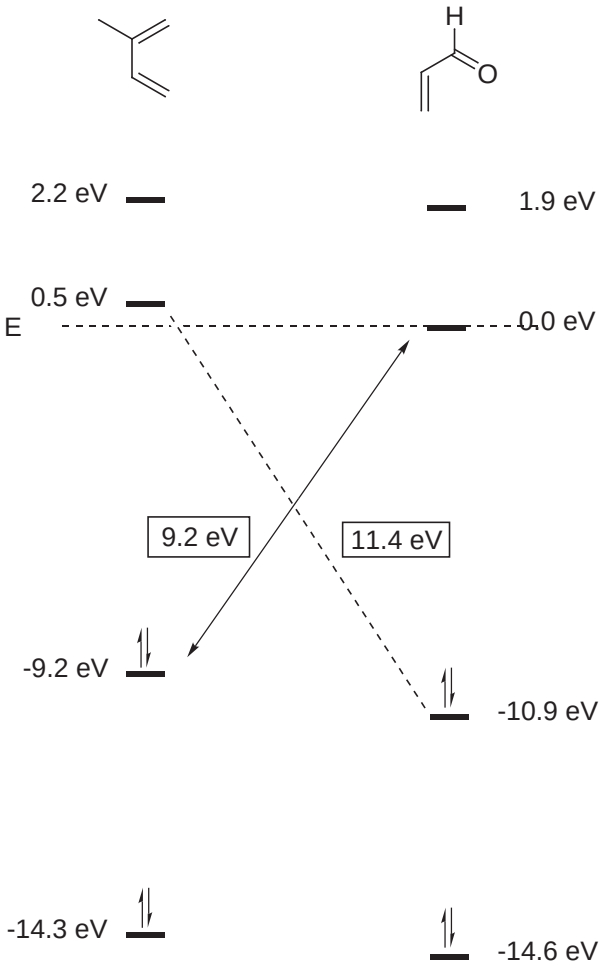
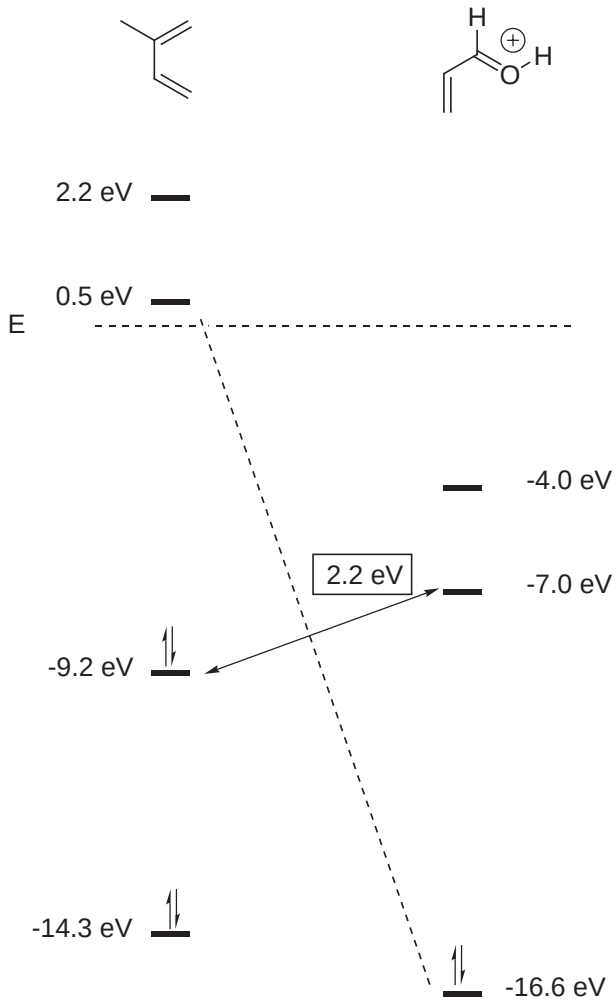
AM1 π-MO's

Thermal reaction



Model for Lewis acid-catalyzed reaction



$HOMO_{diene}$ - $LUMO_{dienophile}$ energy difference is controlling factor for normal Diels-Alder reaction - making this E difference smaller will increase rate of reaction. For uncatalyzed reaction, ΔE = 9.2 eV

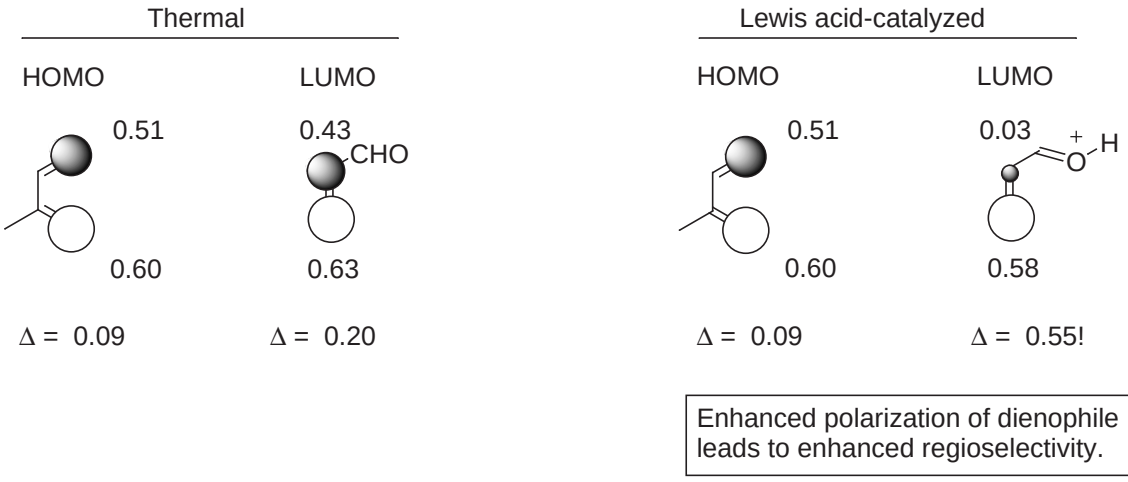
For catalyzed reaction, ΔE = 2.2 eV

-21.6 eV

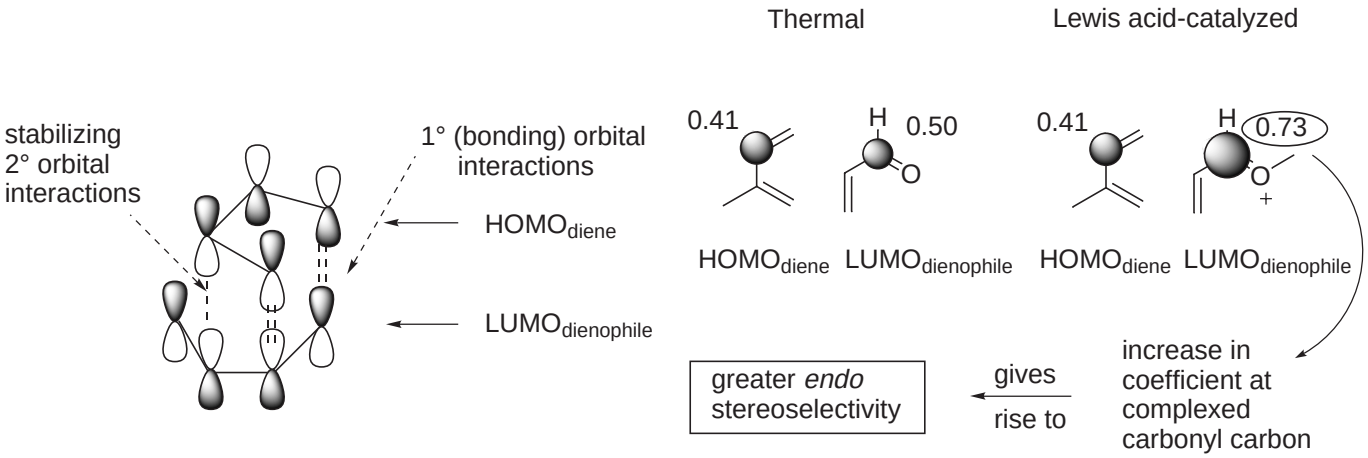
Rate:
-Lewis acids catalyze reaction by lowering energy of π MO's of dienophile.
-Importantly, the LUMO of the dienophile becomes much lower in energy.

Rate increase by Lewis acid catalysis due to lowering of E of $LUMO_{dieneophile}$.

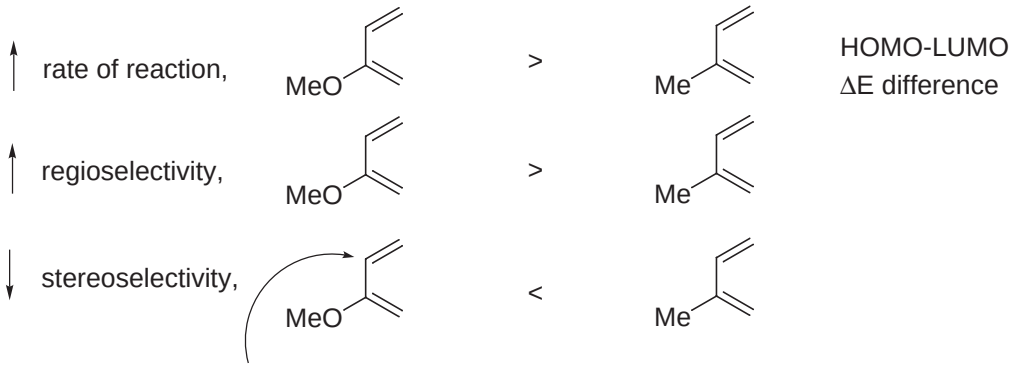
Regioselectivity:



Diastereoselectivity (*endo* cycloaddition):

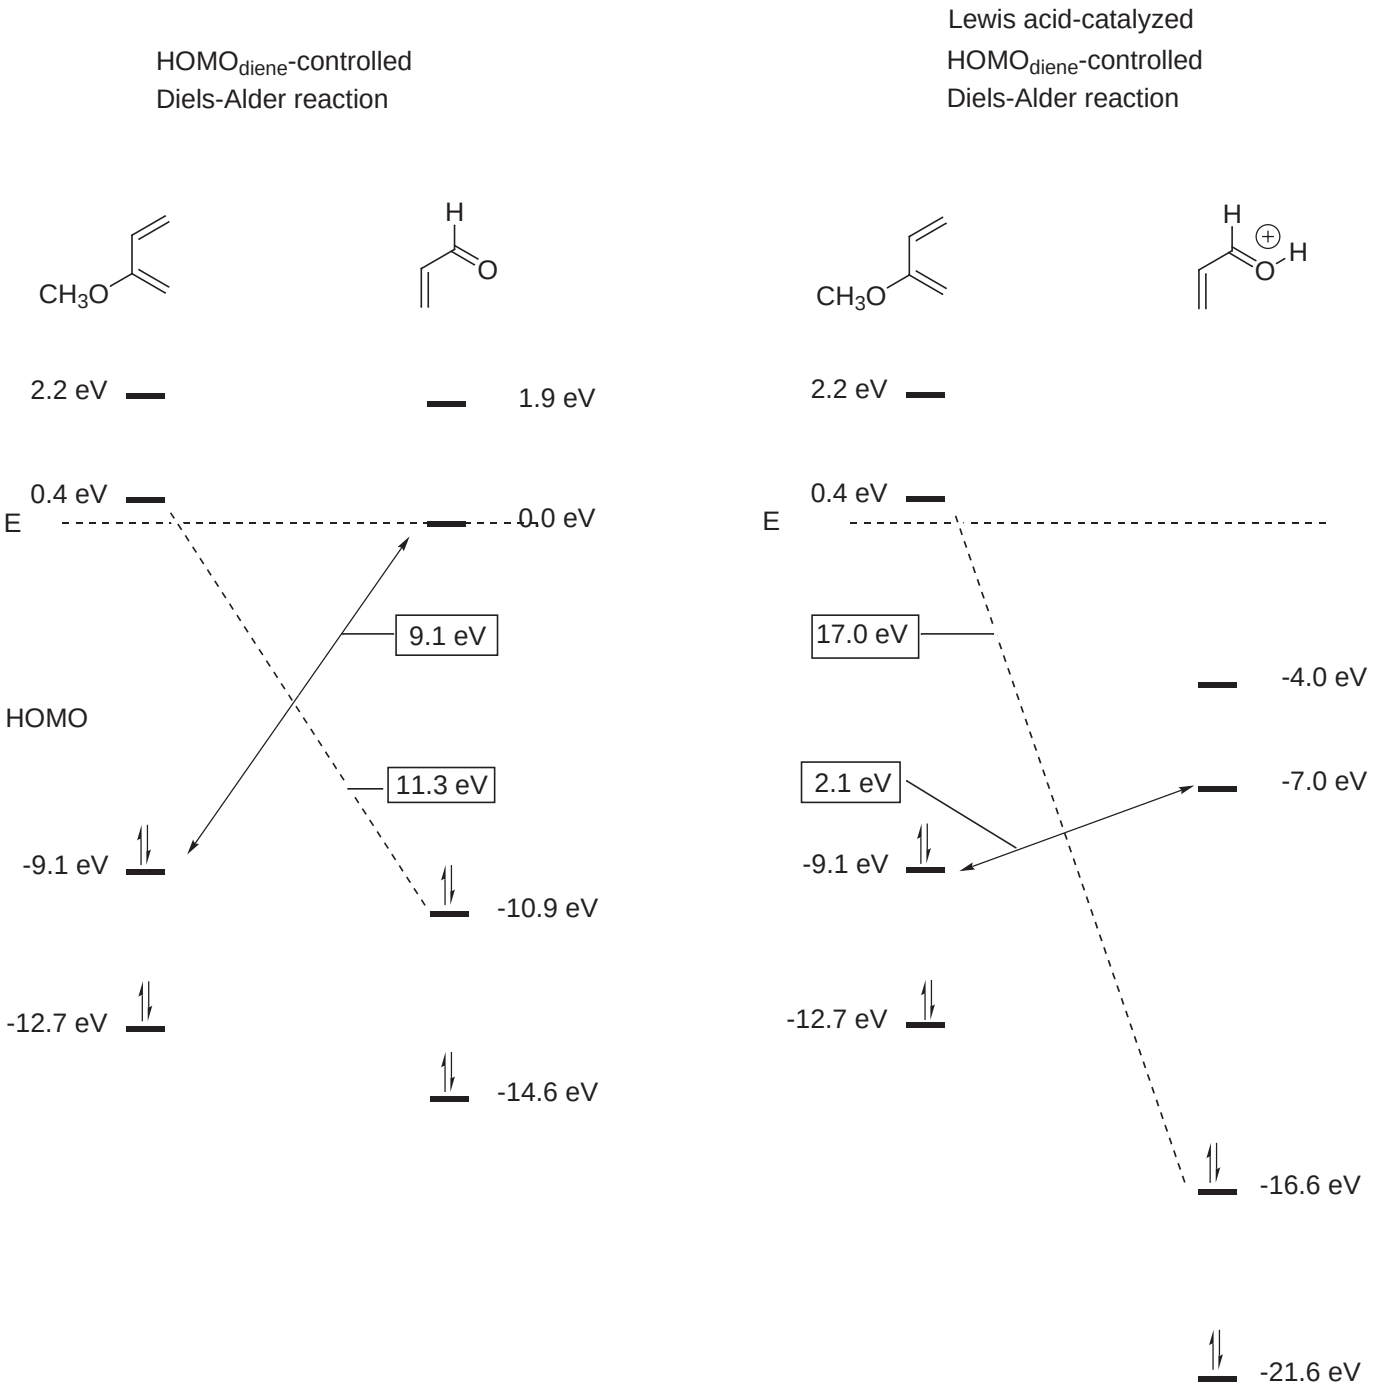


NOTE comparison of



due to smaller (relative) coefficient at C3 of diene.

AM1 Results



Note: 1 eV = 23.06 kcal/mol, so difference of 0.1 eV is 2.3 kcal/mol and is significant in $\Delta\Delta G^{\ddagger}$.

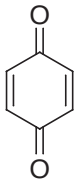
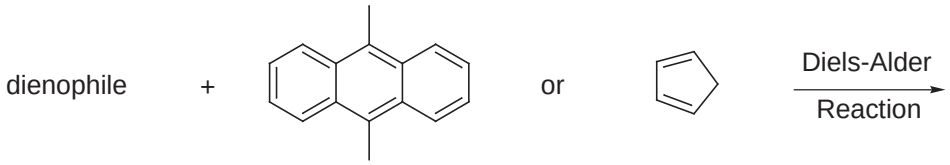
Boger *J. Am. Chem. Soc.* **1995**, *117*, 12452.

d. Quinones are outstanding dienophiles



e. Number and position of electron-withdrawing groups



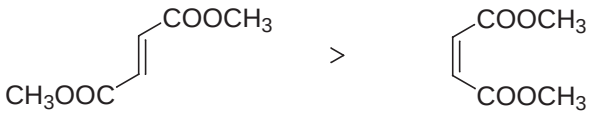
Dienophile	Relative Rates	
	1.3×10^9	4.3×10^7
	5.9×10^5	4.8×10^5
	1.3×10^4	4.5×10^4
	0.09	1
	215	74
	140	31

NOTE: large increase in rate by addition of one more complementary EWG

NOT as large an increase upon addition of one more noncomplementary EWG

f. *cis* vs. *trans* Dienophiles

-In polar (or radical) processes, *cis* isomer reacts faster than *trans*, but in Diels-Alder reaction:

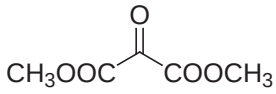


one additional destabilizing steric interaction

-The relative rates of such *cis* vs. *trans* reactions are sometimes used to distinguish between concerted cycloadditions vs. nonconcerted stepwise reactions.

g. Heterodienophiles: typically electron-deficient

e.g.



2π component

$HOMO_{diene}$-controlled Diels-Alder reaction.

h. Heterodienes: typically electron-deficient

e.g.

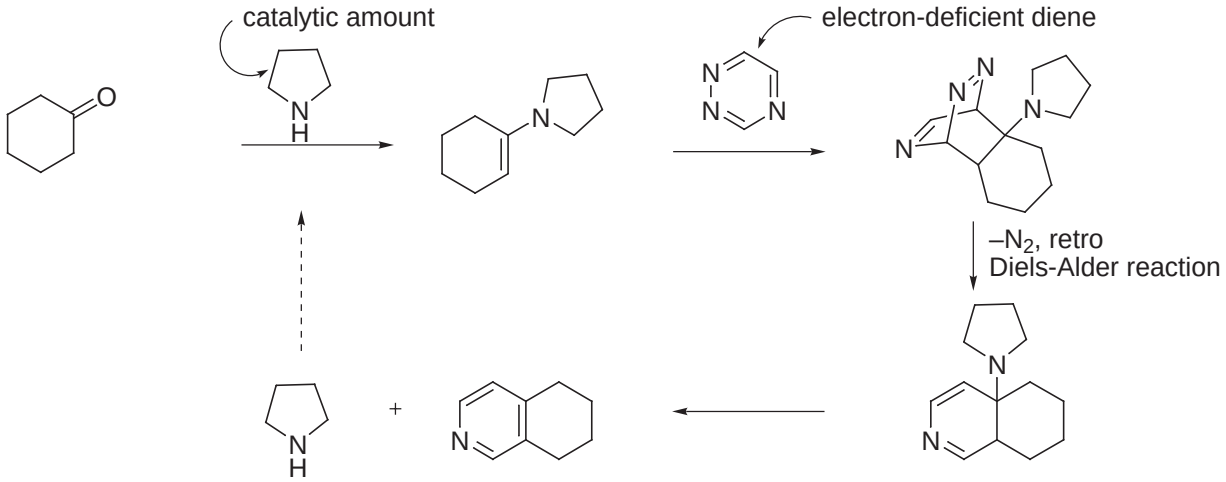
4π component

$LUMO_{diene}$-controlled Diels-Alder reaction.

introduction of heteroatom makes diene electron-deficient.

Note: Dienophiles can also be generated *in situ*:

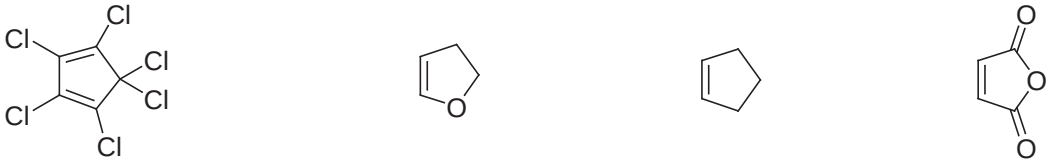
Boger *J. Org. Chem.* **1984**, *49*, 4050.



Catalytic Diels-Alder reaction
Boger *J. Org. Chem.* **1982**, *47*, 895.

i. Dienophiles which are not electron-deficient

(1) Participate in inverse electron demand Diels-Alder reactions:



k_{rel} = 12 2 1

McBee *J. Am. Chem. Soc.* **1954**, *77*, 3858.
Jung *J. Am. Chem. Soc.* **1977**, *99*, 5508.

(2) Can be used in cation-radical Diels-Alder reactions.

(3) Also include the behavior of strained olefins.

j. Dienophile equivalents

-Many specialized dienophiles have been developed which react well in the Diels-Alder reaction and which serve to indirectly introduce functionality not otherwise directly achievable.

inaccessible dienophile	equivalent dienophile	
		 acetylene  acetylene  		J. Am. Chem. Soc. **1958**, *80*, 209. *J. Org. Chem.* **1988**, *53*, 5793. *J. Org. Chem.* **1984**, *49*, 4033.

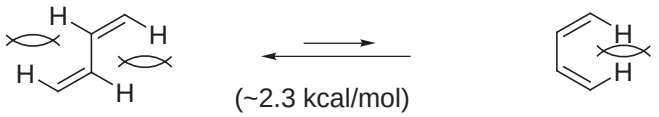
11. Diene

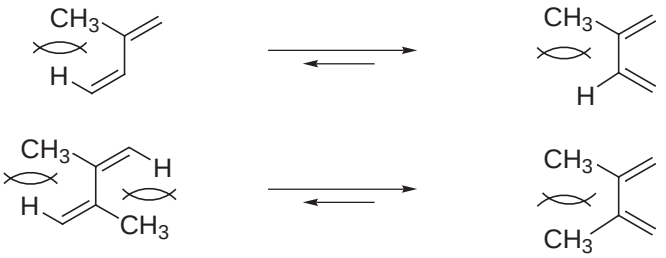
-Dienes must adopt an s-cisoid (s-*Z*) conformation to react.



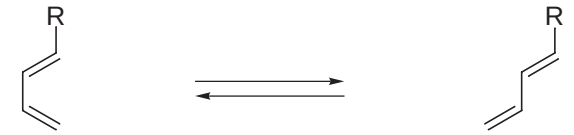
s-*E* (transoid) s-*Z* (cisoid)

Cisoid conformation of diene is favored with:

(a) 2- and/or 3-substitution

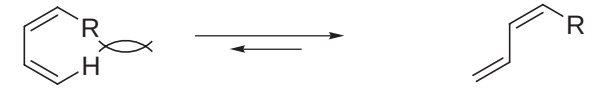


(b) 1-Substituted dienes



E-diene

But

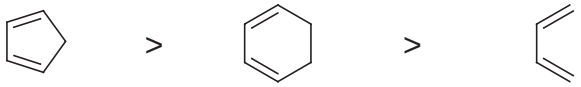


Z-diene not very reactive

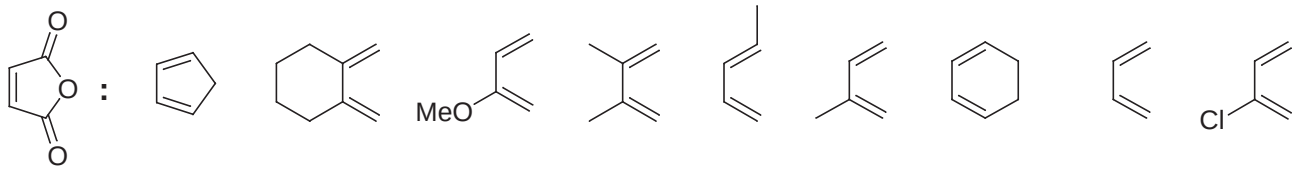
10^5 rate difference for *cis* and *trans*

can be used to separate *cis* and *trans* isomers of dienes

(c) And, by locking the diene into cisoid conformation



reaction rates for cyclic dienes are faster

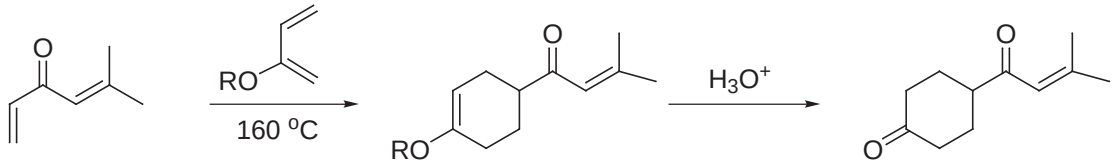


k_{rel} =	1348	110	12	5	3.3	2.2	2	1	0.1

12. Functionalized Dienes

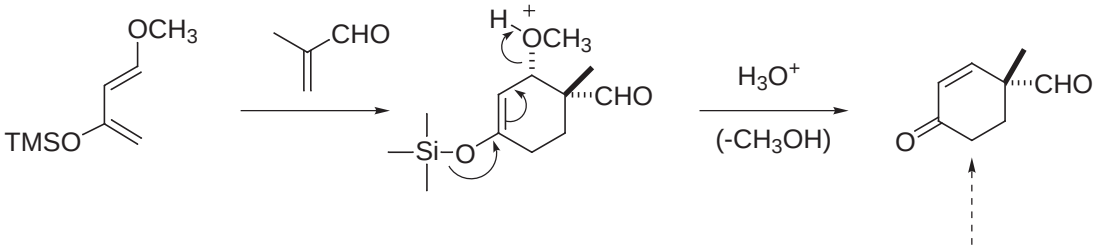
Review: Petrzilka, Grayson *Synthesis* **1981**, 753.

-Diels-Alder reaction with introduction of useful functionality



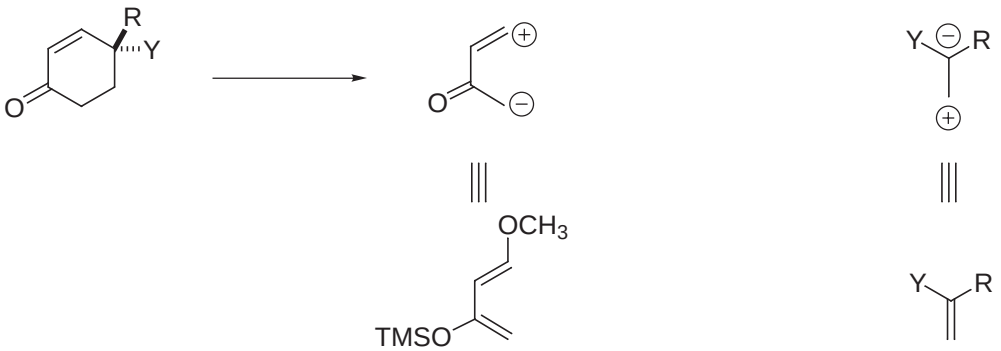
Danishefsky *J. Am. Chem. Soc*. **1979**, *101*, 6996.

-Danishefsky:

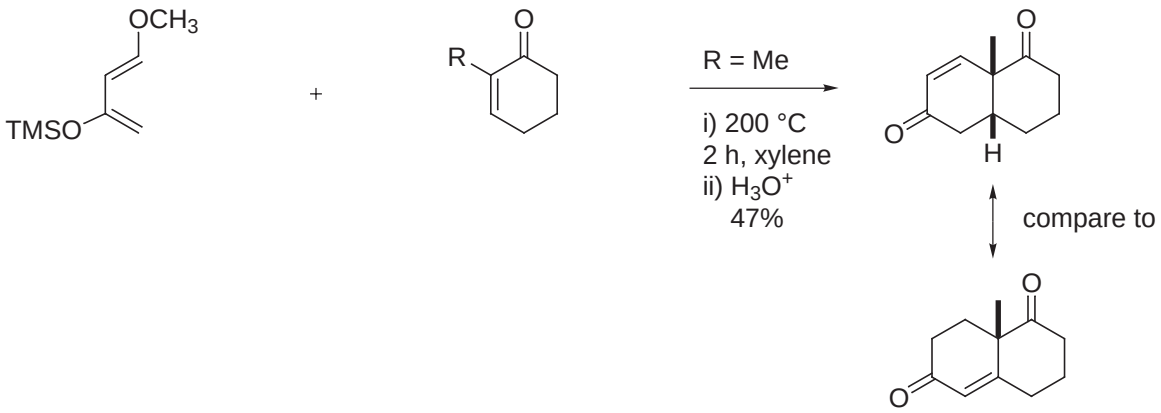


So an alternative disconnection for α,β-unsaturated enones

looks like a Robinson annulation product



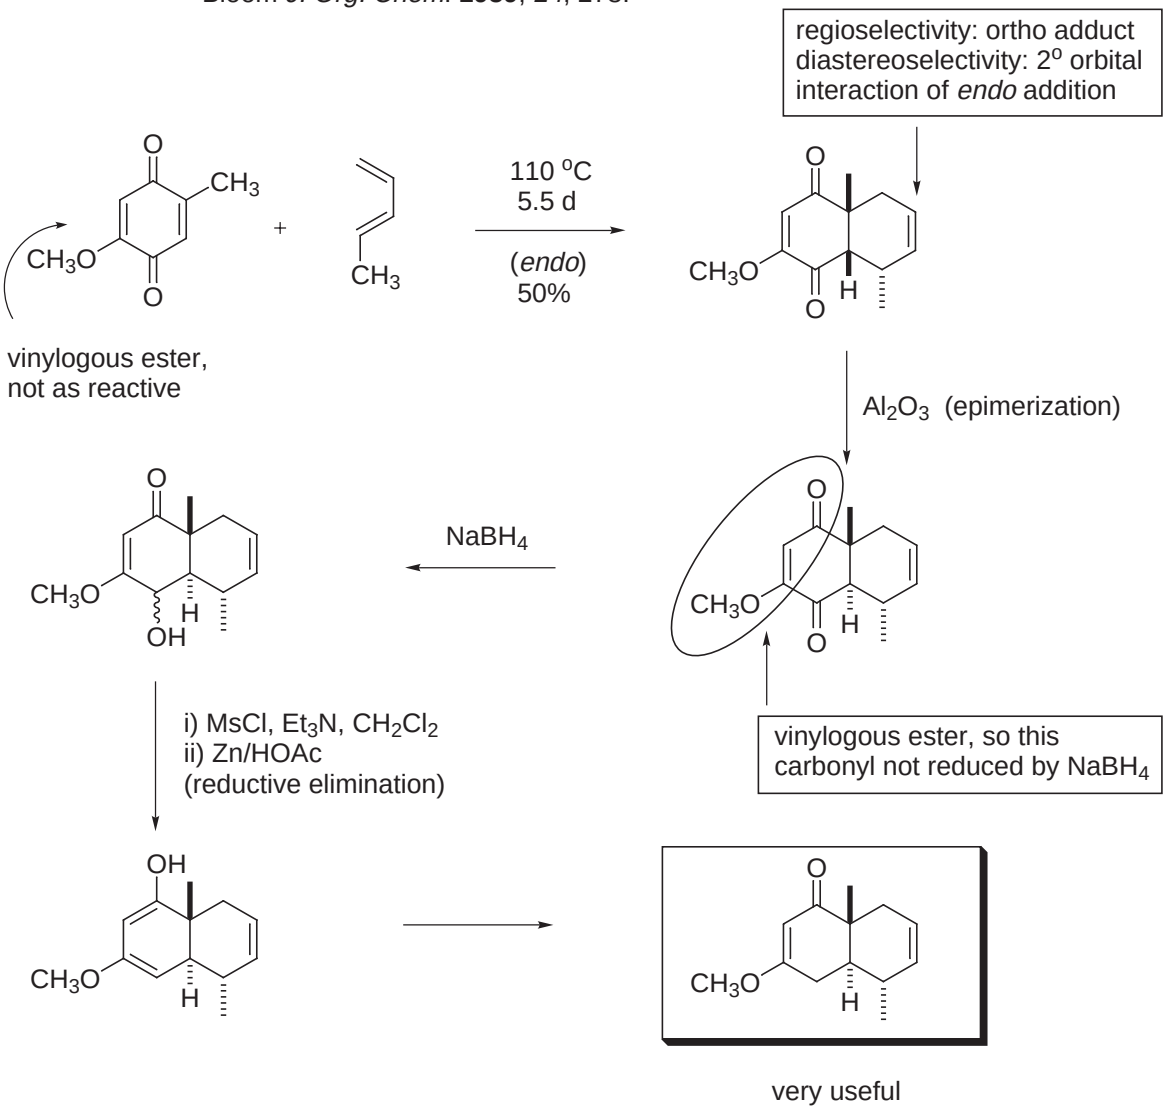
Example:



Wieland-Miescher Ketone

see also: Danishefsky *J. Am. Chem. Soc*. **1979**, *101*, 6996, 7001, 7009, 7013.

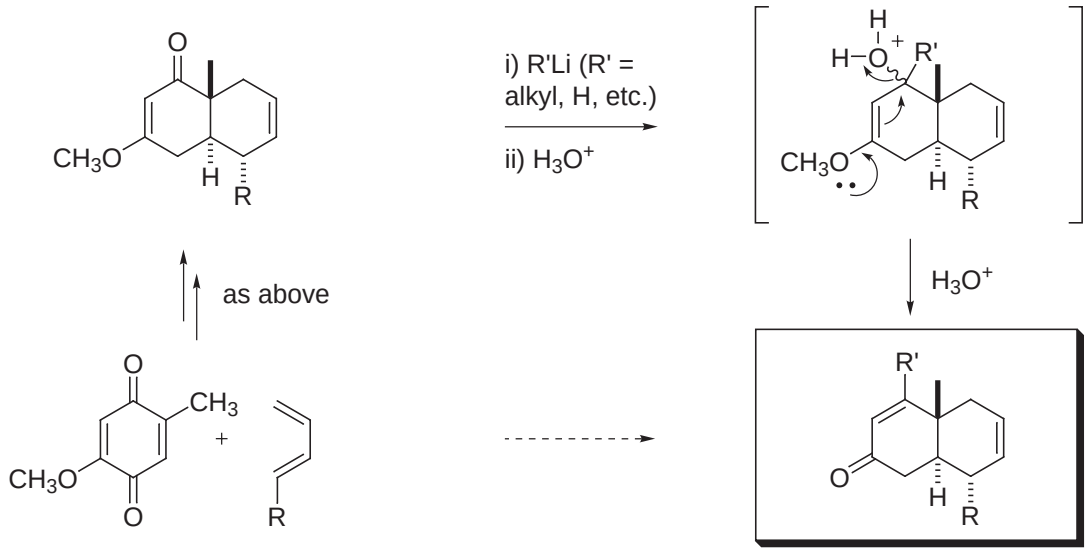
Companion Strategy: Woodward *J. Am. Chem. Soc*. **1952**, *74*, 4223;
Bloom *J. Org. Chem*. **1959**, *24*, 278.



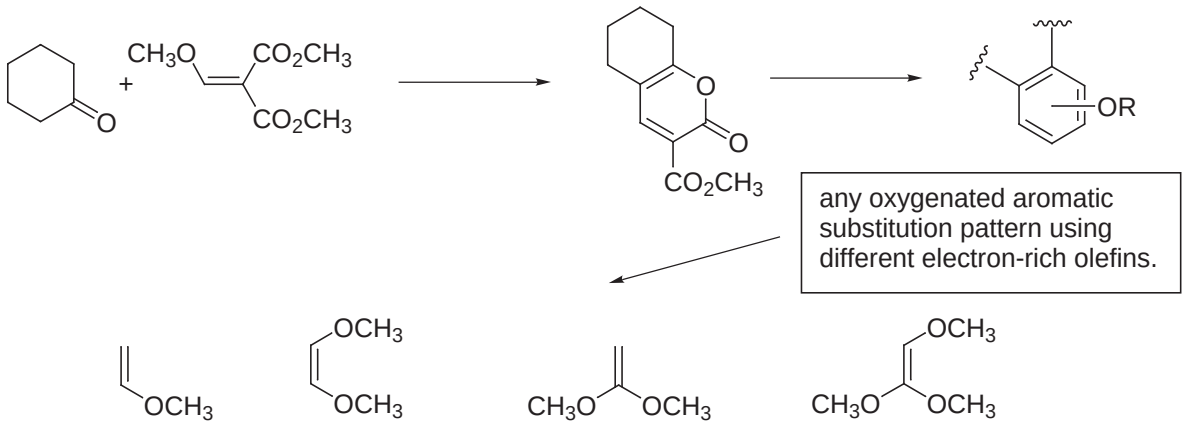
very useful

See also: Robinson *J. Am. Chem. Soc*. **1961**, *83*, 249.
Orchin, Butz *J. Org. Chem*. **1943**, *8*, 509.
Kishi *Tetrahedron Lett*. **1970**, 5127.
Kakushima *Can. J. Chem*. **1976**, *54*, 3304.

Can also add nucleophiles (RLi, H^-) to the "vinylogous ester" carbonyl:

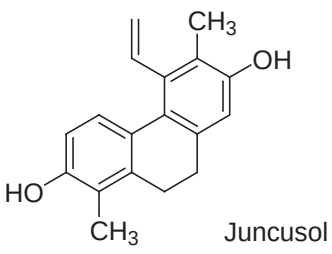


-Aromatic Annulation

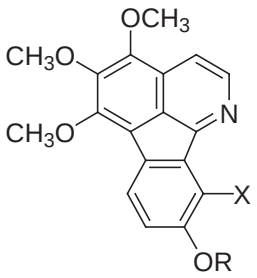


Boger *J. Org. Chem*. **1984**, *49*, 4033, 4045 and 4050.

Use of aromatic annulation in total synthesis:

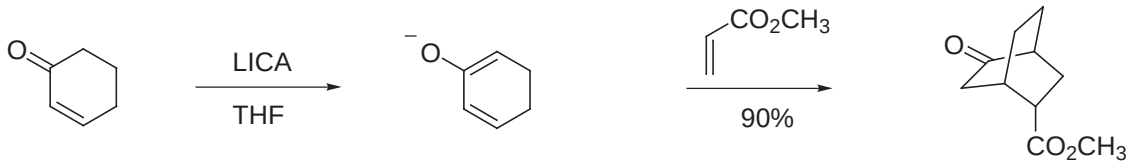


Juncusol



Rufuscine, Imelutine
Norrufuscine
X = H, OR

Heteroatom Substituted Dienes:



Diels-Alder or Michael-Michael Reaction

14. Intramolecular Diels-Alder Reactions

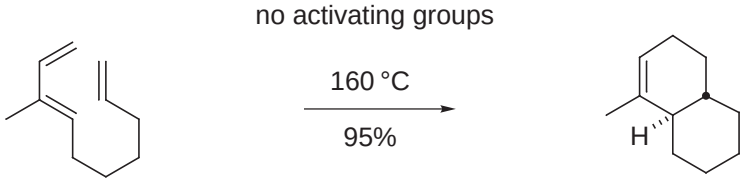
Review: Ciganek *Org. Reac.* **1984**, *32*, 1.
Jung *Synlett* **1990**, 186.
Thomas *Acc. Chem. Res.* **1991**, *24*, 229.
Weinreb *Acc. Chem. Res.* **1985**, *18*, 16.
Oppolzer *Comprehensive Organic Synthesis*, Vol. 5; 315.

A. General Considerations:

-less negative $\Delta S^{\ddagger}$, which accelerates reaction and results in milder reaction conditions.

-naturally affects regioselectivity and diastereoselectivity.

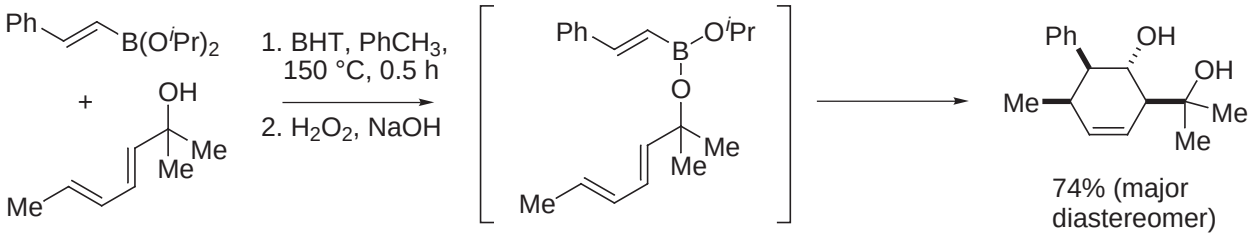
-extends Diels-Alder reaction to include systems which are normally unreactive.



Wilson *J. Am. Chem. Soc.* **1978**, *100*, 6289.

B. Notable applications in synthesis:

-tethered intramolecular Diels-Alder reactions

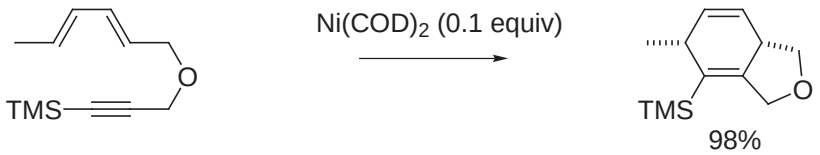


Batey *J. Am. Chem. Soc.* **1999**, *121*, 450.

-metal-catalyzed intramolecular Diels-Alder reactions

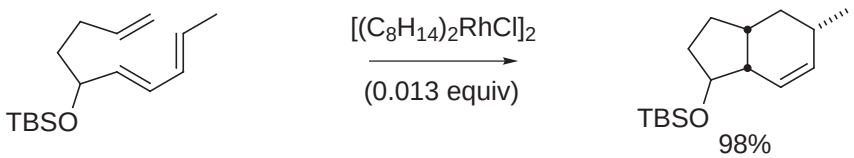
An emerging group of transition-metal mediated [4 + 2] cycloadditions are under development.

Ni-catalyzed



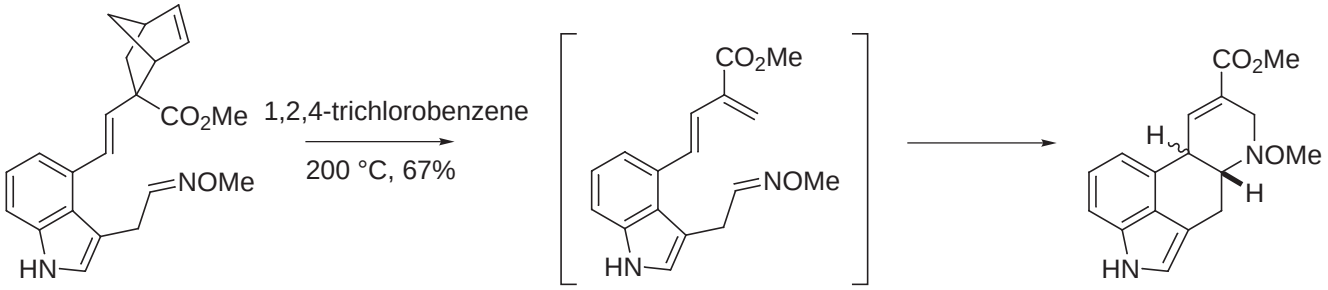
Wender *J. Am. Chem. Soc.* **1989**, *111*, 6432.

Rh-catalyzed

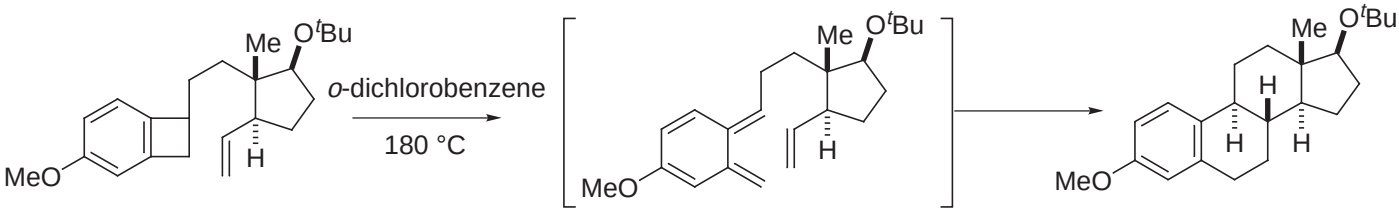


Livinghouse *J. Am. Chem. Soc.* **1990**, *112*, 4965.

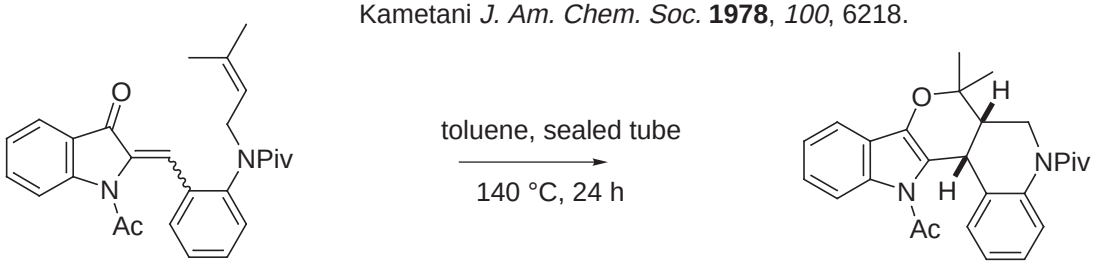
-applications in total synthesis



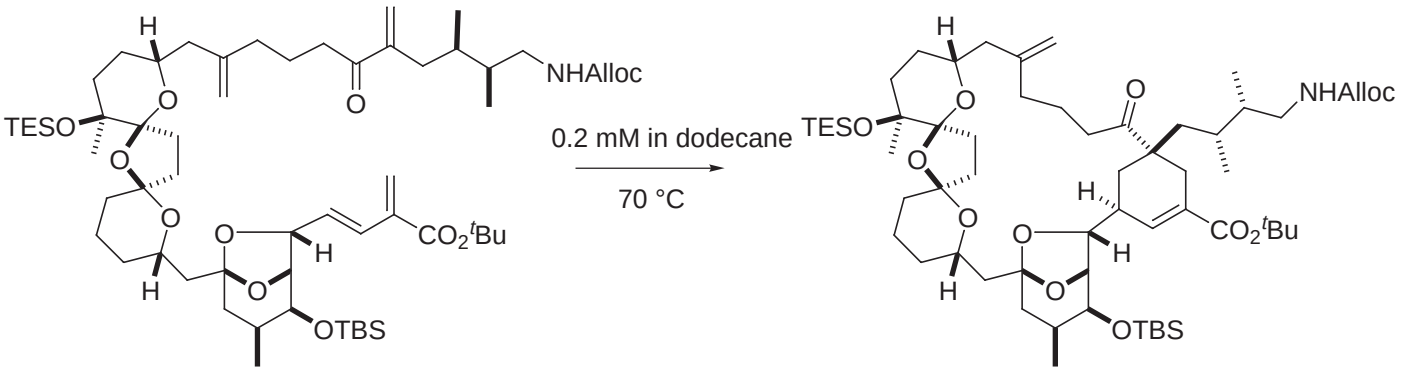
Oppolzer *Helv. Chim. Acta* **1981**, *64*, 478.



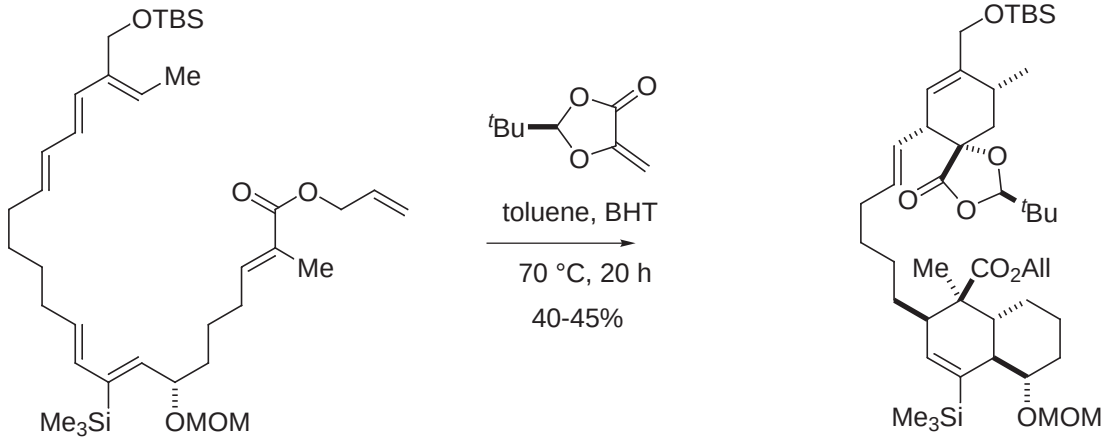
Kametani *J. Am. Chem. Soc.* **1978**, *100*, 6218.



Merour *Synlett* **1998**, 1051.



Kishi *J. Am. Chem. Soc.* **1998**, *120*, 7647.

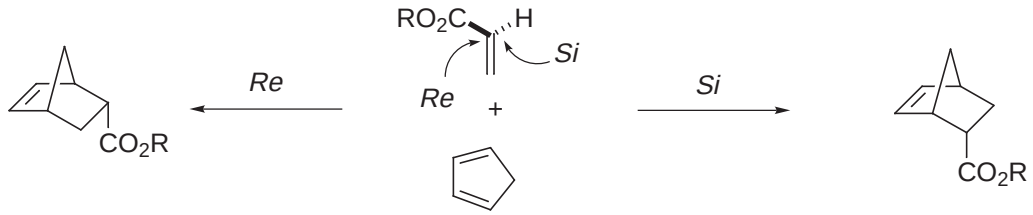


Roush *J. Am. Chem. Soc.* **1998**, *120*, 7411.

15. Asymmetric Diels-Alder Reaction

A. General considerations

-Unsymmetrically substituted dienes or dienophiles have enantiotopic faces. Even with exclusive *cis-endo* addition and regioselectivity, products occur as a pair of enantiomers.

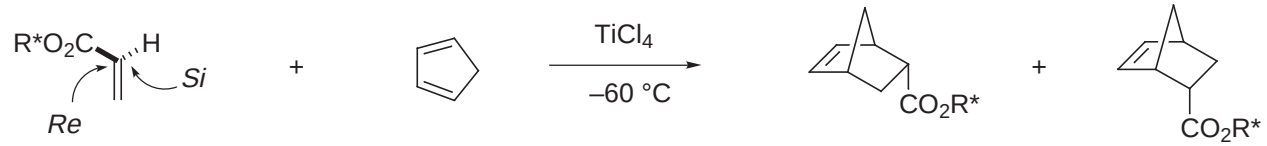


-There are three possible ways to obtain one of the enantiomers in excess:

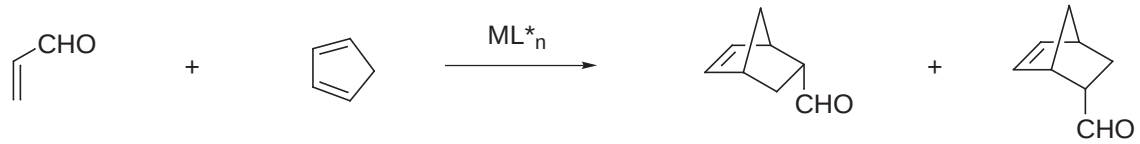
a) using chiral dienes.
b) using chiral dienophiles.
c) using chiral Lewis acid catalysts.
In addition, double stereoselection can be realized in many situations.

-Comparison of chiral substrate vs. chiral catalyst

use of a chiral substrate (chiral diene or dienophile): a stoichiometric amount of chiral auxiliary R* is needed and its introduction before and removal after the Diels-Alder reaction are neccessary.



use of a chiral catalyst: usually 0.1 equiv. is enough to introduce chirality and the catalyst can be recovered from the reaction mixture and reused.



B. Chiral dienophiles

Review: Oppolzer *Angew. Chem., Int. Ed. Eng.* **1984**, *23*, 876.
Ager and East *Asymmetric Synthetic Methodology*; CRC Press: New York, 1996.

-Chiral dienophiles provide the vast majority of the examples of asymmetric Diels-Alder reactions.

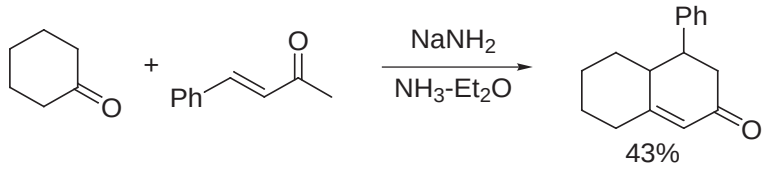
B. Robinson Annulation

Reviews House pp. 606-613.
M. Jung, *Tetrahedron* **1976**, *32*, 3.
Org. React. **1959**, *10*, 179.
Org. React. **1968**, *16*, 3.
Synthesis **1976**, 777.
Synthesis **1969**, 49.

R. Robinson was awarded the 1947 Nobel Prize in Chemistry for his work on the synthesis of natural products, especially steroids and alkaloids. Notably, he was also the first to address the issue of reaction mechanisms with applications of valence theory to reaction mechanisms, and is credited with the first use of the curved arrow to indicate electron movement. His synthesis of tropinone (1917) is viewed by many to represent the first natural product total synthesis from simple precursors (succindialdehyde, acetone, and methylamine).

Robinson *J. Chem. Soc.* **1917**, 762. (tropinone)

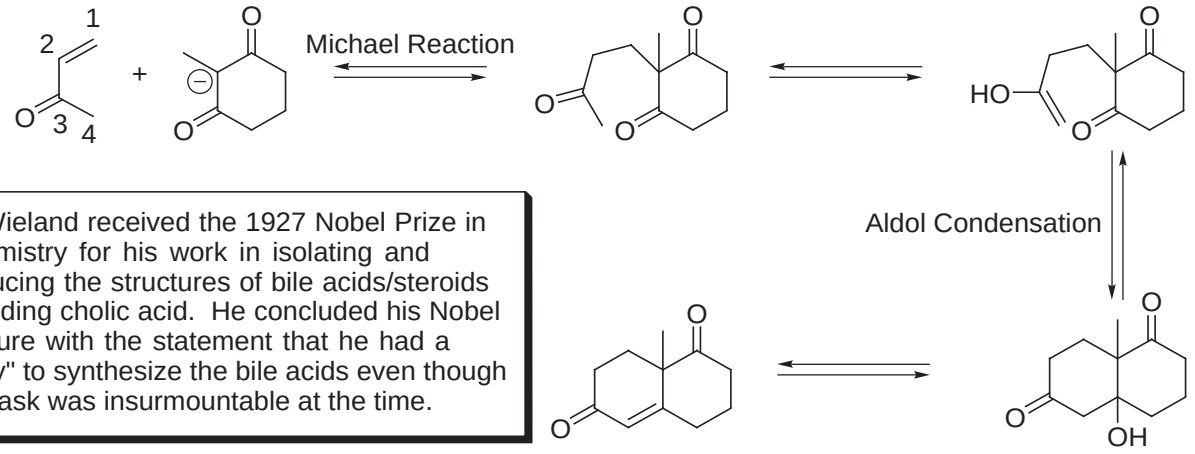


Robinson *J. Chem. Soc.* **1935**, 1285.

Generated a great deal of interest and subsequent work because of relationship to steroid synthesis.

1. Scope

- Formally, a [4 + 2] condensation approach



H. Wieland received the 1927 Nobel Prize in Chemistry for his work in isolating and deducing the structures of bile acids/steroids including cholic acid. He concluded his Nobel Lecture with the statement that he had a "duty" to synthesize the bile acids even though the task was insurmountable at the time.

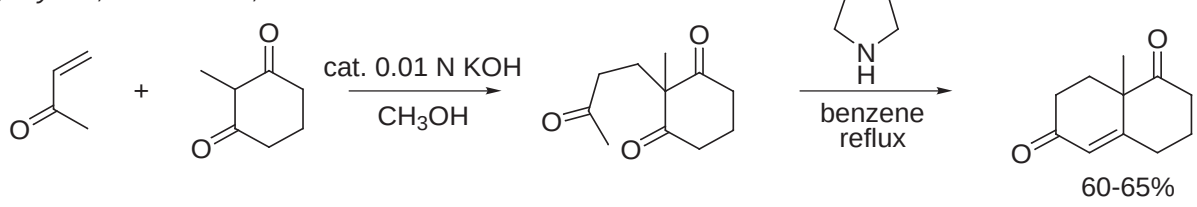
Wieland-Miescher ketone

Wieland and Miescher *Helv. Chim. Acta* **1950**, *33*, 2215.

- Alternative "[3 + 3] Robinson Annulation"

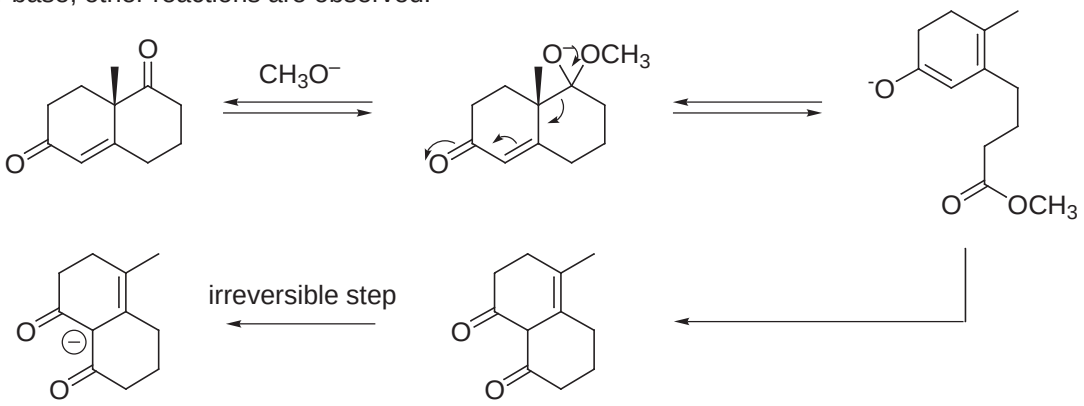
Both the [4 + 2] and [3 + 3] approaches were first generalized by Robinson *J. Chem. Soc.* **1937**, 53.

- *Org. Synth.*, Coll. Vol. 5, 486.

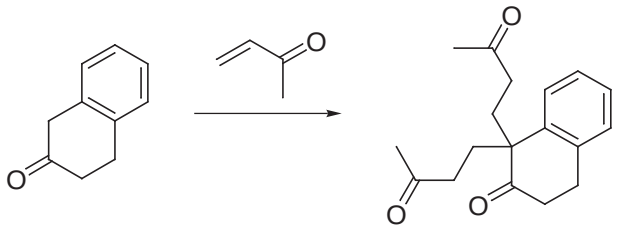


60-65%

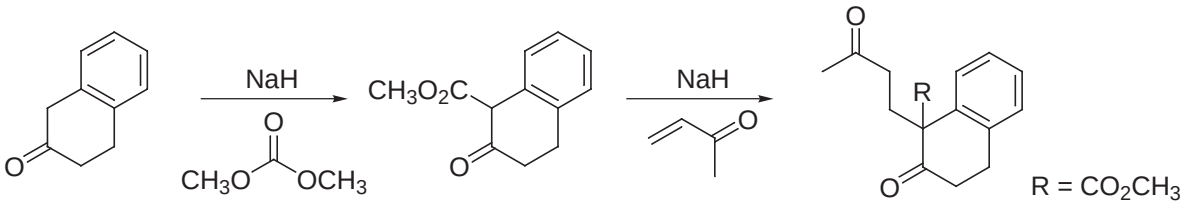
- With stronger base, other reactions are observed:



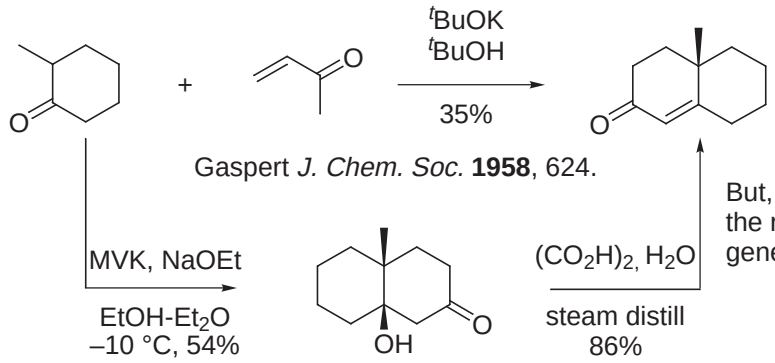
- Double addition of MVK sometimes a problem, especially at more acidic sites.



-Solutions

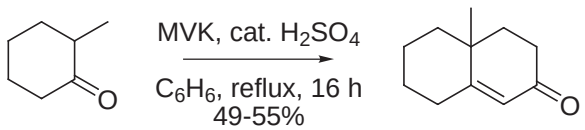


- For the preparation of the useful octalone derivative, the low yield is acceptable since it is prepared from readily available materials.



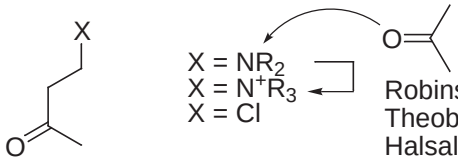
Marshall *J. Org. Chem.* **1964**, *25*, 2501.

At low temperature, MVK polymerization is slow and Michael reaction OK,
but not sufficiently vigorous for elimination, so the reaction is conducted in two steps.



Heathcock and McMurry *Tetrahedron Lett.* **1971**, 4995.

- Alternatives to methyl vinyl ketone: MVK difficult to employ due to tendency to polymerize



Robinson *J. Chem. Soc.* **1937**, 53.
Theobald *Tetrahedron* **1966**, *22*, 2869.
Halsall *J. Chem. Soc.* **1964**, 1029.

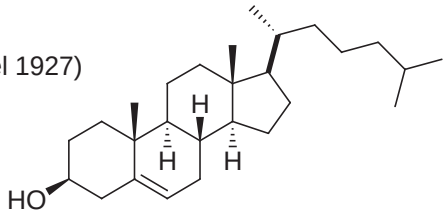
6. Steroid Synthesis

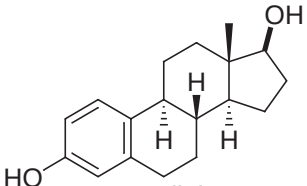
Steroid synthesis: Woodward (Nobel 1965), Robinson (Nobel 1947)
Isolation methods: Chromatography
Conformational analysis: Barton (Nobel 1969)
UV spectroscopy: Woodward, Fieser
ORD: Djerassi
Biosynthesis theory: Bloch and Lynen (Nobel in Med. 1964), Cornforth (Nobel 1975)

1. Cholesterol

Isolation: 1812
Structure, wrong!, Windaus (Nobel 1928) and Wieland (Nobel 1927)
1932, correct planar connectivity (Wieland)
1947, stereochemistry
1952, absolute stereochemistry

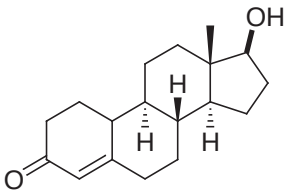


2. Sex Hormones



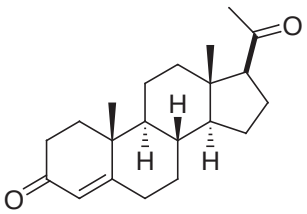
Estradiol

The hormone responsible for female development and maintenance of reproductive organs and secondary sex characteristics.
Pure material isolated 1929, E. Doisy (St. Louis Univ.) and A. Butenandt (Gottingen, Nobel 1939)
4 tons of sow ovaries: 25 mg



Testosterone

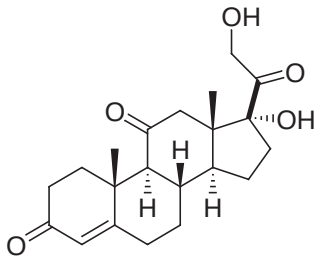
The male sex hormone
1931, Butenandt isolated androsterone (metabolite of testosterone)
15,000 L of men's urine: 15 mg
1935, testosterone isolated from 100 kg bull testicles: 10 mg, E. Laquer
1939, planar structure elucidated by Butenandt, Ruzicka (Nobel 1939)



Progesterone

The pregnancy hormone: maintains proper uterine environment for development of fetus, inhibits further ovulation, nature's contraceptive.
1934, isolation and planar structure, Butenandt
50,000 sows to provide 625 kg ovaries: 20 mg

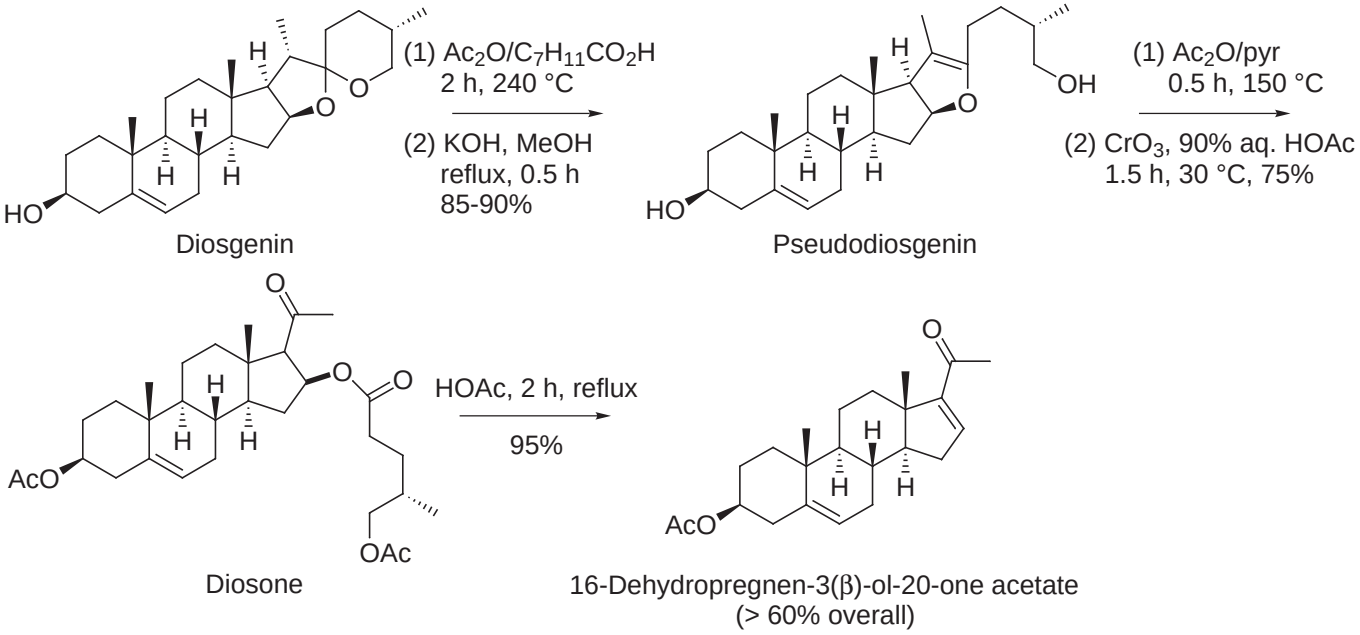
3. Cortisone



Structure: 1935-38, Kendall, Reidstein, Wintersteiner
from adrenal cortex of 1.25 million cattle
1952, 36 step synthesis via degradation of bile acids (Sarett, Merck)
1949, Hench and Kendall (Mayo Clinic), 1950 Nobel with Reinstein for anti-arthritic activity
1951, Djerassi (Syntex), synthesis from Mexican yam steroid
1951, Upjohn microbial process for C11 oxidation of progesterone

Natural steroid hormones are present in such trace amounts in mammals that it is not a practical source. Synthetic steroids, e.g. 19-nor steroids, became commercially important.

Russell E. Marker (Syntex, Penn. State)
Degradation of sapogenins and other plant products
J. Am. Chem. Soc. **1947**, *69*, 2167.
Diosgenin is obtained from the Mexican diocorea plant (Mexican yams).

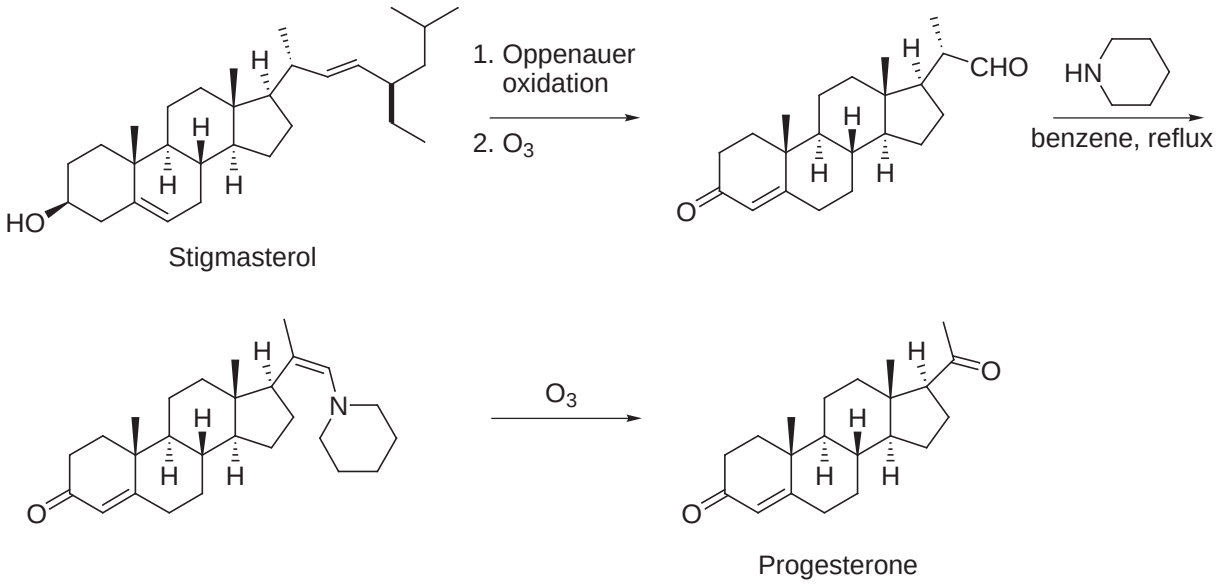


Diosgenin — Pseudodiosgenin

Diosone — 16-Dehydropregnen-3(β)-ol-20-one acetate (> 60% overall)

Dehydropregnenolone is easily transformed to progesterone in 3 steps:
(1) H_2, Pd-C (2) hydrolysis (3) Oppenauer oxidation: cyclohexanone, $Al(O^iPr)_3$

Upjohn avoided attempted monopoly by use of stigmasterol obtained from soybeans:



Stigmasterol

Progesterone

Estrone

Total Synthesis of Cortisone

R. B. Woodward received the 1965 Nobel Prize in Chemistry for "Contributions to the Art of Organic Synthesis" and the award preceded the total synthesis of vitamin B_{12} carried out in collaboration with Eschenmoser, the principles of orbital symmetry conservation (Hoffmann Nobel Prize in 1981), the Wilkinson structure determination of ferrocene (Nobel 1973) carried out with Woodward, and the collaborative delineation of the steroidal biosynthesis involving stereoselective cation-olefin cyclizations in collaboration with Bloch (Nobel 1964). Woodward changed synthesis from application of empirical reactions to a mechanistic foundation for predicting substrate reactivity (rates, stereoselectivity) and designed this rationale into the preplanned synthesis. The results were stunning with unattainable objectives falling one after another: quinine (1944), patulin (1950), cholesterol (1951), cortisone (1951), lanosterol (1954), lysergic acid (1954), strychnine (1954), reserpine (1956), chlorophyll (1960), tetracyclines (1962), colchicine (1963), cephalosporin C (1966), most before the wide spread usage of ^{1}H NMR. Breathtaking natural product structure determinations: penicillin (1945), strychnine (1948), patulin (1949), terramycin (1952), aureomycin (1952), cervine (1954), magnamycin (1956), gliotoxin (1958), oleandomycin (1960), streptonigrin (1963), and tetrodotoxin (1964) also preceded the reliance on ^{1}H NMR. The formal total synthesis of vitamin B_{12} was completed in 1972 in collaboration with A. Eschenmoser (>100 postdoctoral fellows) and synthetic cobyric acid was converted to vitamin B_{12} in 1976.

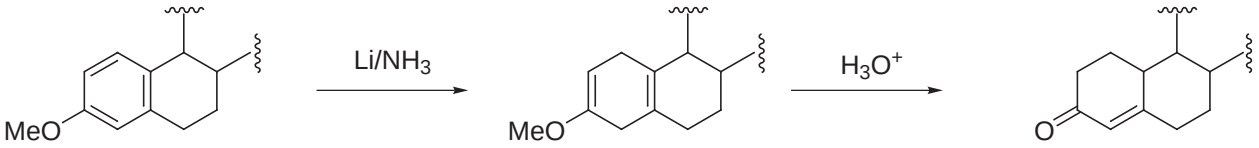
C. Birch Reduction

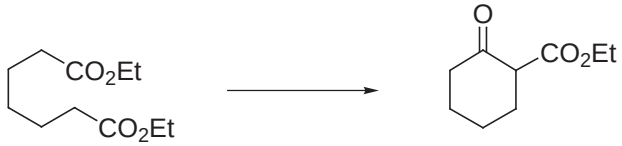


Robinson annulation-type product

- See the discussion in the sections on the Birch reduction and the Robinson annulation.
- Allows an aromatic ring to be incorporated into a synthesis and converted into a useful, nonaromatic ring system.

D. Dieckmann Condensation

- An intramolecular Claisen condensation, see enolate section for a more detailed discussion.



E. Intramolecular Nucleophilic Alkylation

- Powerful approach to closure of rings

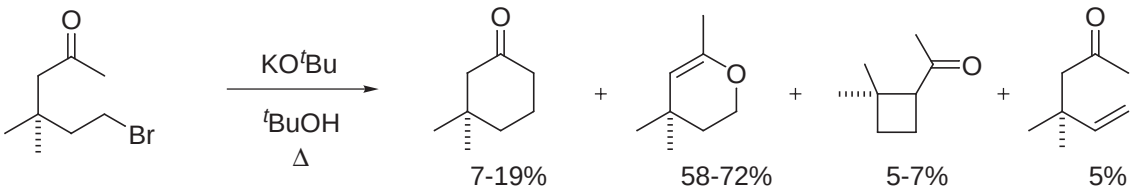
Examples:

- Kinetic enolate generation (Note: *O*-alkylation may compete).

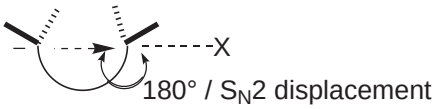
- Gem dimethyl effect facilitates cyclization

House *J. Org. Chem.* **1978**, *43*, 700.

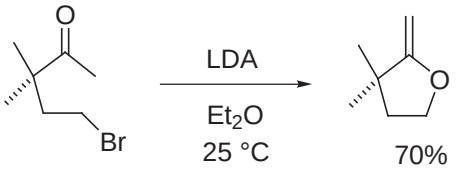
- Versus thermodynamic enolate generation (Note: *O*-alkylation may compete).

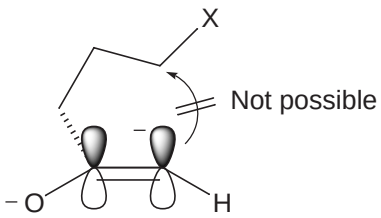


- Closure subject to stereoelectronic control.

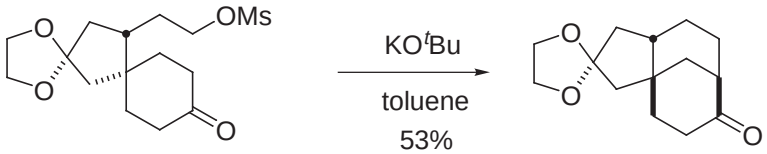


- Note Baldwins Rules
Preceded by Eschenmoser
Helv. Chim. Acta **1970**, *53*, 2059.





- Examples



Gibberelic Acid, Corey
J. Am. Chem. Soc. **1979**, *101*, 1038.

3. Background

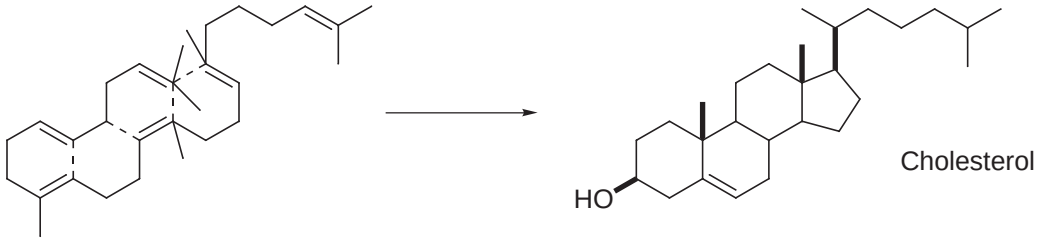
Squalene cyclization first suggested as a biosynthetic precursor to cholesterol

Heilbrow, Kann, and Owens *J. Chem. Soc.* **1926**, 1630.

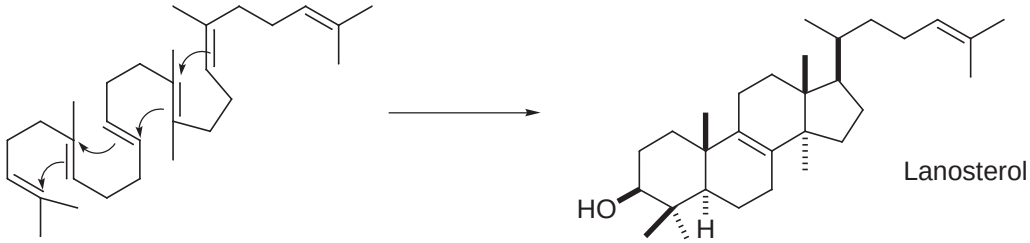
Robinson *Chem. Ind.* **1934**, *53*, 1062.

J. L. Goldstein and M. S. Brown received the 1985 Nobel Prize in Medicine for their discoveries concerning the regulation of cholesterol metabolism.

- Robinson's proposal



- Correct cyclization scheme



- Lanosterol was proposed in 1953 by Woodward and Block.

- Experimental verification that cholesterol is biosynthesized from squalene was developed independently by

Block *J. Biol. Chem.* **1953**, *200*, 129.

Cornforth *Biochem. J.* **1954**, *58*, 403.

Biochem. J. **1957**, *65*, 94.

K. Block received the 1964 Nobel Prize in Medicine for his discoveries concerning the mechanism and regulation of the cholesterol and fatty acid metabolism.

J. W. Cornforth received the 1975 Nobel Prize in Chemistry jointly with V. Prelog for outstanding intellectual achievement on the stereochemistry of reactions catalyzed by enzymes.

- Stork-Eschenmoser hypothesis: the *trans-anti-trans* stereochemistry of the steroids and many terpenoids is a consequence of a concerted polyene cyclization.

Cyclization about a *trans* olefin

Cyclization about a *cis* olefin

- Anti addition of a carbocation and nucleophilic olefin on opposite faces of a π-bond analogous to *trans* electrophilic addition to alkenes. Therefore, cyclization of a *trans* olefin leads to a *trans* ring fusion and cyclization of a *cis* olefin leads to a *cis* ring fusion.

4. Key Publications

- Initial experimental demonstrations of multiple cascade cyclizations and the Stork-Eschenmosher steroid-type cyclizations:

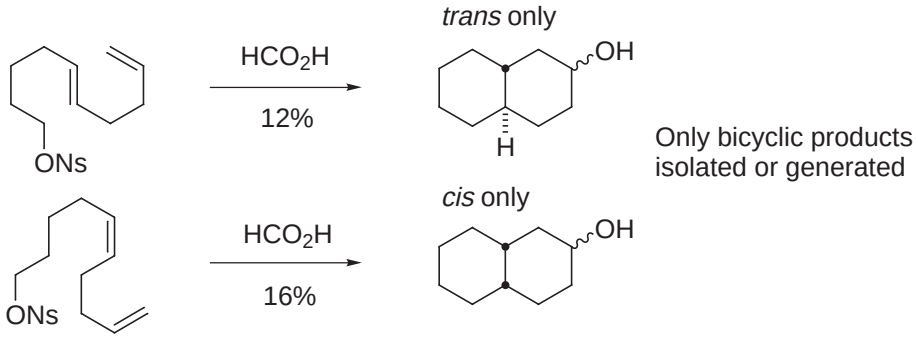
Stork and Burgstahler *J. Am. Chem. Soc.* **1955**, *77*, 5068.

Eschenmoser and Arigoni *Helv. Chim. Acta* **1955**, *38*, 1890.

First disclosed in lectures and proposals as early as 1950, but experimental verification was difficult.

- First clear verification of Stork-Eschenmoser hypothesis.

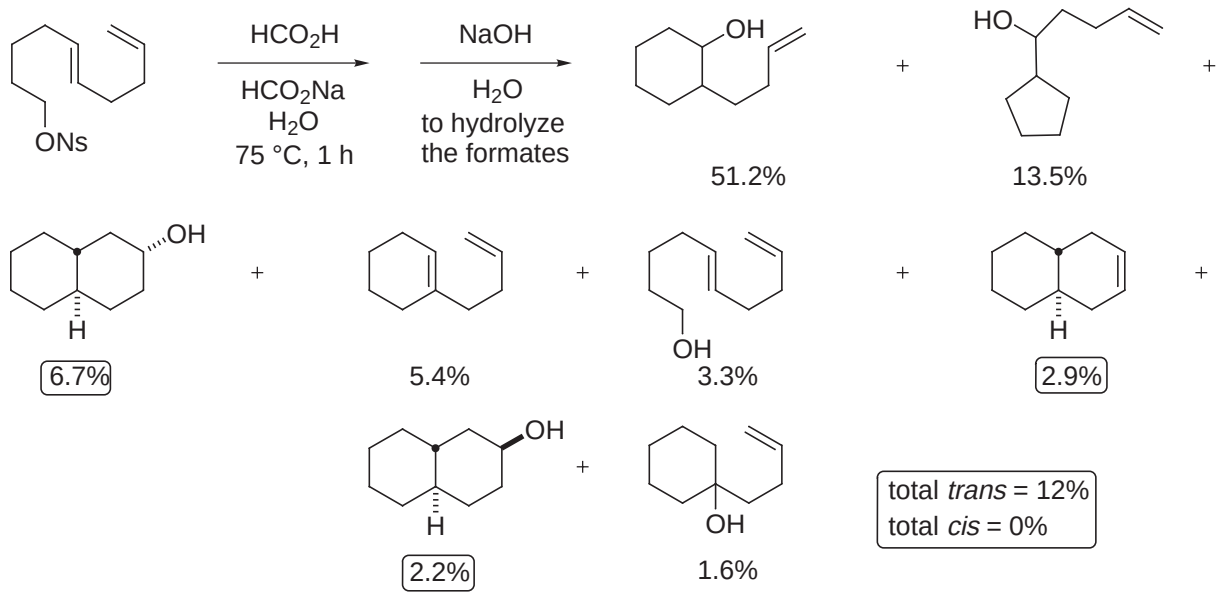
Johnson *J. Am. Chem. Soc.* **1964**, *36*, 1959.
J. Am. Chem. Soc. **1965**, *30*, 1735.



5. Three Stages of Reaction

- Initiation
- Cyclization
- Termination

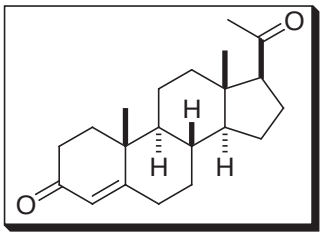
- Mechanistically all three may take place simultaneously or stepwise paths may be involved.
- Depends on the nature of the substrate and the reaction medium.
- Without careful control, the formation of many products will result in a complex mixture.
- For example: Johnson verification of Stork-Eschenmoser hypothesis.

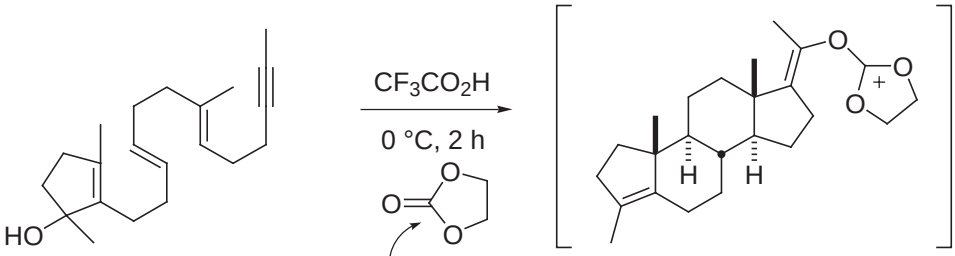


- Much effort expended to control the reaction through mild, selective and efficient initiation and termination.

8. Synthesis of Progesterone

Johnson
J. Am. Chem. Soc. **1971**, *93*, 4332.
J. Am. Chem. Soc. **1978**, *100*, 4274.





- Tertiary allylic alcohol for initiation
- Substituted alkyne for termination
- 5-*exo-dig* vs. 6-*endo-dig*

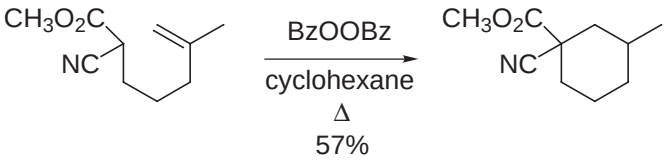
5. Radical-Olefin Cyclizations

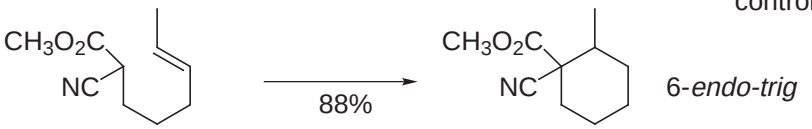
a. Representative Examples

- Concurrent with Johnson's investigation of cation-olefin cyclizations, Julia initiated radical-olefin cyclization studies.



Julia *Compt. rend.* **1960**, *251*, 1030.

Reversible, thermodynamically controlled reactions.



6-*endo-trig*

b. Reactivity and Regioselectivity

- Relative rates of addition to  $PO(OEt)_2$: typical electron-deficient olefin.

	CH_3•	CH_3CH_2•	CH_3OCH_2•	$(CH_3)_2CH$•	$(CH_3)_3C$•
k_{rel} =	1	1	2.7	4.8	24

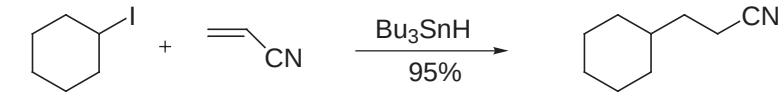
- Alkyl radicals are regarded as nucleophilic.

Steric Effects on Addition Regioselectivity

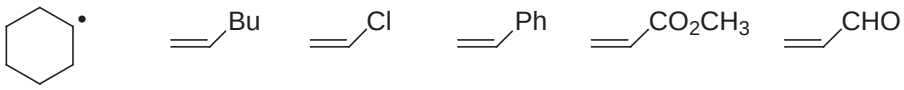
olefin	% addition to: Ca	Cb	k_{rel}
 a b	>95	<5	1.16
 a b	>95	<5	18.4
 a b	>95	<5	2 x 136
 a b	50	50	2 x 0.50
 a b	50	50	2 x 0.63
 a b	>95	5	15
 a b	<5	>95	13.9

	k_{rel}
R = H	1
R = ^{t}Bu	0.24
	5 x 10^{-5}

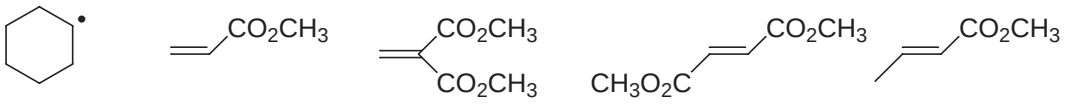
β-substitution strongly decelerates intermolecular addition with activated acceptors



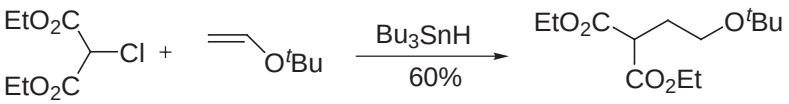
Nucleophilic radical — Electrophilic acceptor alkene



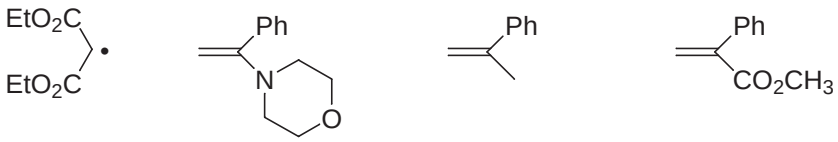
k_{rel}	1.0	8.4	84	3000	8500



k_{rel}	1.0	150	5	0.01

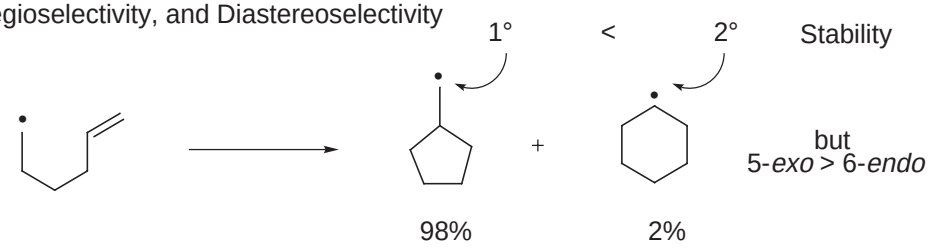


Electrophilic radical — Nucleophilic acceptor alkene

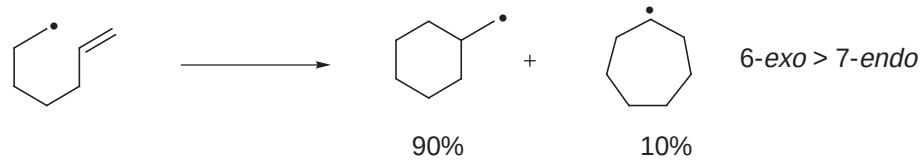


k_{rel}	23	3.5	1

c. Cyclization Rates, Regioselectivity, and Diastereoselectivity



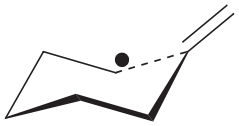
Beckwith *J. Chem. Soc., Chem. Commun.* **1974**, 472.
Beckwith *J. Chem. Soc., Chem. Commun.* **1980**, 484.



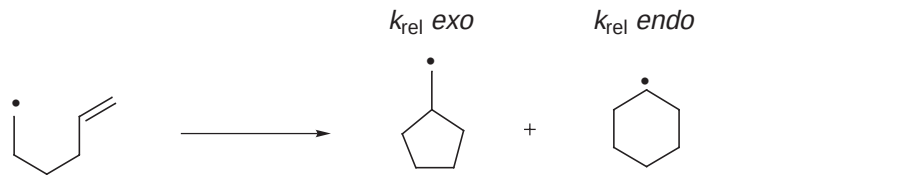
- Chair-like transition state subject to stereoelectronic and kinetic control rather than thermodynamic control.

≡ 5-*exo*

Stereochemical features of substitution can be rationalized and predicted based on these models.



≡ 6-*exo*



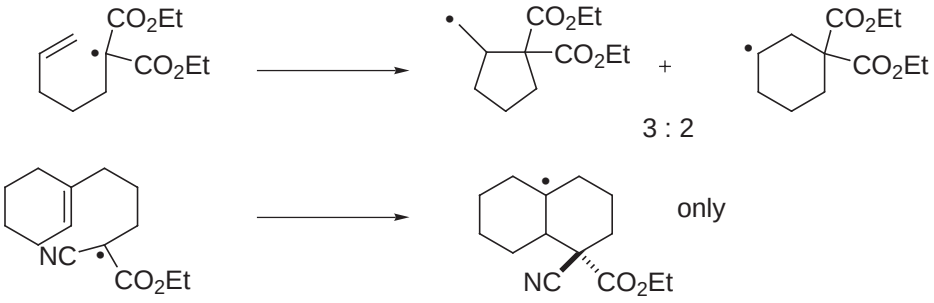
- Linker chain effects

	k_{exo}/k_{endo}	
X = CH_2	0.55	*endo* > *exo*
X = O	38.6	*exo* >> *endo*

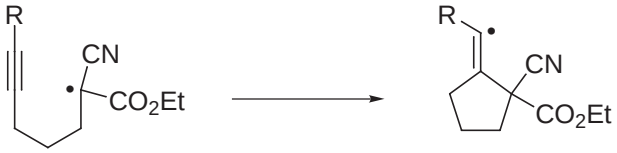
	k_{rel}	
R = H	1	gem dimethyl effect
R = CH_3	10	

	ring size	*k*	k_{rel}	
n = 1	5	~10^5 s^{-1}	1	*exo* >> *endo*
n = 2	6	~10^4 s^{-1}	0.1	
n = 3	7	~10^2 s^{-1}	0.001	7-membered ring closure so slow that reduction competes.

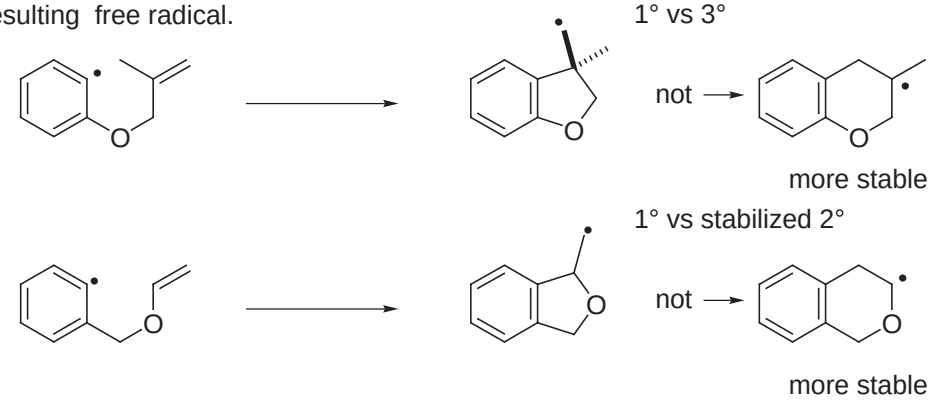
- Stabilized radicals participate in reversible cyclizations and the thermodynamic product is observed.



- Alkynyl radicals give 5-*exo* closure (stereoelectronic) even with stablized radicals.



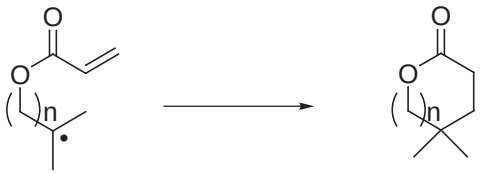
- Note effect of additional sp^2 centers in the linking chain: 5-*exo* closure takes precedence over the overall stability of the resulting free radical.



- Closure onto carbonyls possible

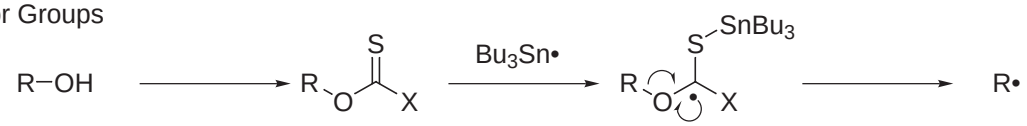
6-*exo* HCO > 5-*exo* C=C

- Macrocyclizations are very facile



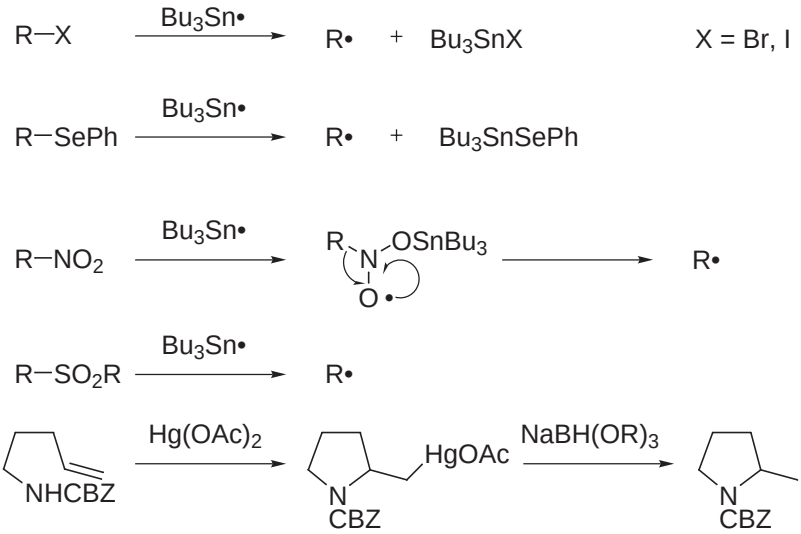
Porter *J. Am. Chem. Soc.* **1987**, *109*, 4976.

d. Initiator Groups



X = SR, OR, SeR

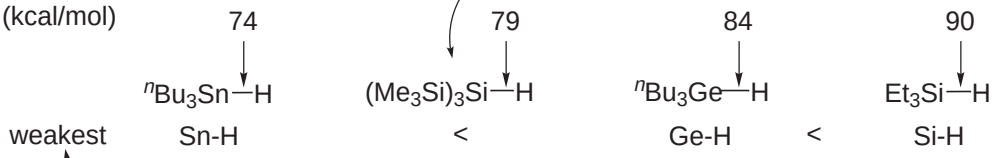
Barton deoxygenation reaction



- Different Initiators

M-H Bond strength (kcal/mol)

Special reagent that increases reactivity of -SiH so it may be used effectively in synthesis.



More competitive reduction by H• abstraction from reagent

Giese *Tetrahedron Lett.* **1989**, *30*, 681.

Ingold *Int. J. Chem. Kinet.* **1969**, *7*, 315.

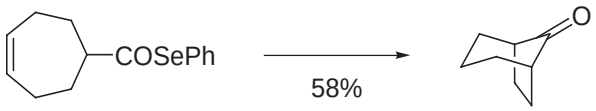
Israel J. Chem. **1997**, *37*, 119. Review

- Examples

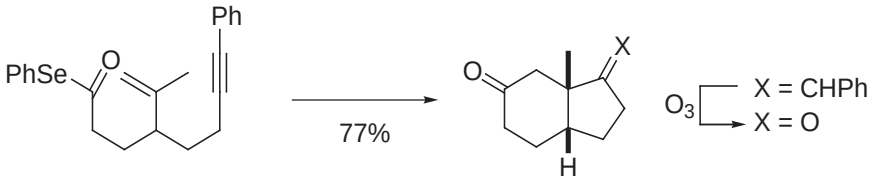
			ring size
X = H	n = 0	81%	5
	n = 1	76%	6
	n = 2	74%	7
X = CO_2CH_3	n = 0	88%	5
	n = 1	84%	6
	n = 2	92%	7

		ring size
n = 0	83%	6
n = 1	71%	7

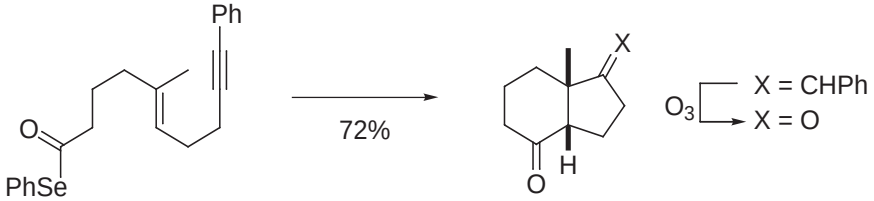


Note: Alkyl and vinyl radicals are subject to faster reduction. Cyclizations such as the above example or those for the formation of 7-membered rings are not very successful, but acyl radicals are much more stable and not subject to competitive reduction.

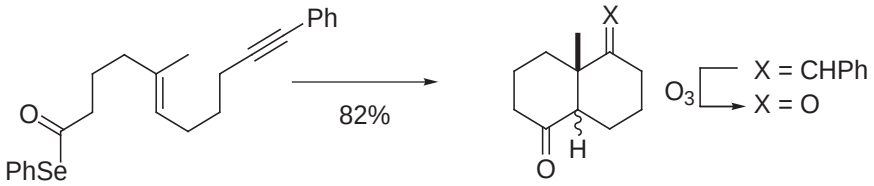
- Tandem Cyclizations



> 98% *cis*

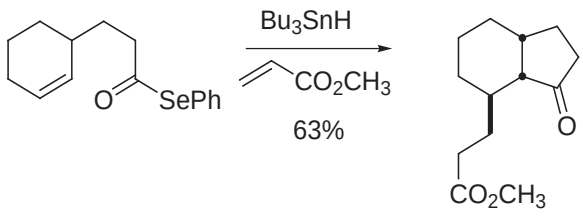


> 97% *cis*

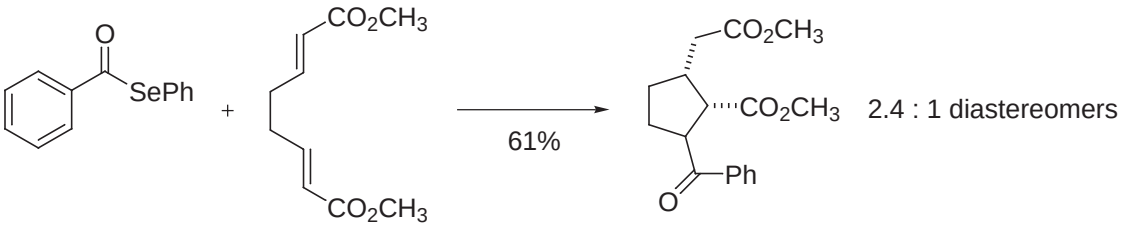


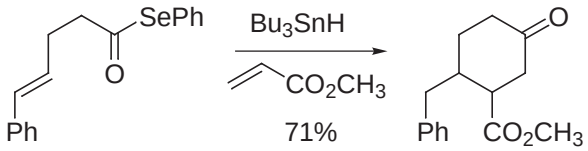
6 : 4 *cis* : *trans*

- Cyclization-Addition Reactions

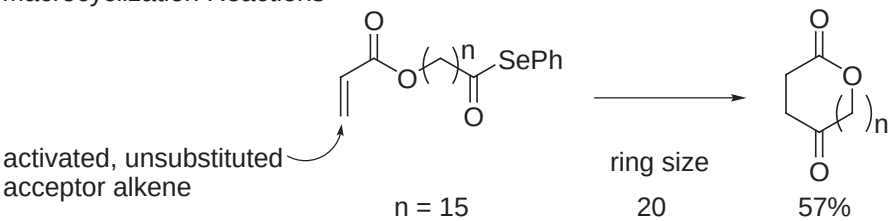


- Addition-Cyclization Reactions





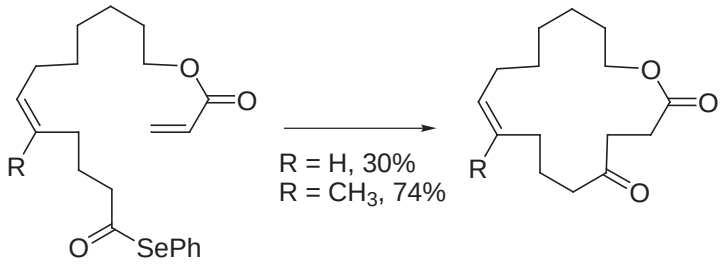
- Macrocyclization Reactions



- decarbonylation very slow
- reduction very slow
- macrocyclization proceeds exceptionally well

	ring size	
n = 15	20	57%
n = 11	16	68%
n = 9	14	55%
n = 7	12	46%
n = 6	11	47%

- Macrocyclization onto activated acceptor is faster than 6-*exo*, 7-*exo* or 6-*endo* closure.
- Competitive with 5-*exo* closure.



- Rearrangement/Ring-enlargement Cyclization

K. 1,3-Dipolar Cycloadditions

Review: *1,3-Dipolar Cycloaddition Chemistry*, Padwa, A., Ed., Wiley: New York, 1984.

- $2\pi^S + 4\pi^S$ Cycloaddition
- Subject to FMO control: can predict regioselectivity and reactivity.

- FMO Control:

(a) Reactivity: ΔE (HOMO/LUMO) and the reactivity of the system is related to the magnitude of the smallest energy gap of the pair of HOMO-LUMO combinations.

(b) Regioselectivity: depends on the magnitude of the orbital coefficients and is determined by the orbital coefficients on the predominant HOMO-LUMO interaction. The largest coefficient on the 1,3-dipole binds to the largest coefficient on the dipolarophile.

(c) Diastereoselectivity: influenced by stabilizing secondary orbital interactions and subject to an endo effect.

(d) Olefin geometry is maintained in the course of the cycloaddition reaction -> concerted reaction.

(e) No solvent effect on the reaction rate -> concerted**.**

(f) No rearrangement products from postulated zwitterion or biradical.

(g) *Trans*-1,2-disubstituted olefins react faster than *cis*-1,2-disubstituted olefins. *cis* olefins are generally more reactive than *trans* olefins in ionic or radical addition reactions.

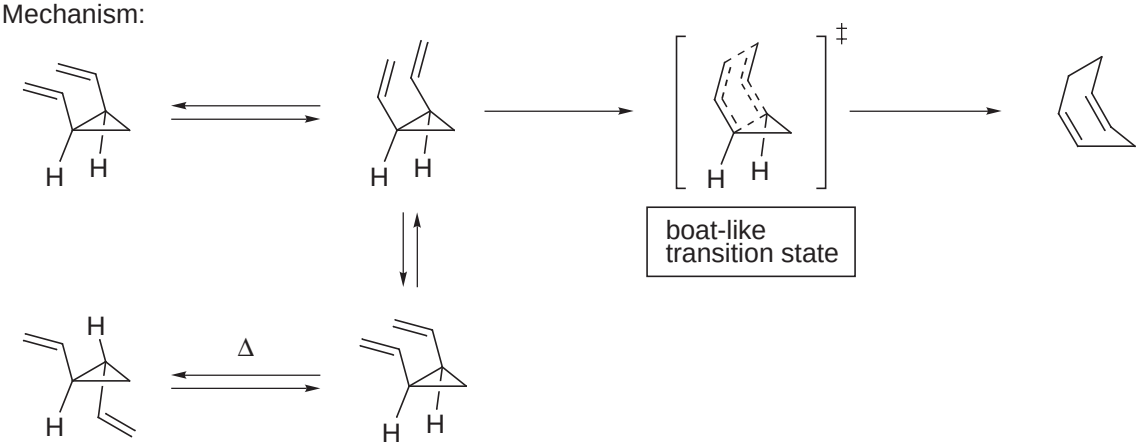
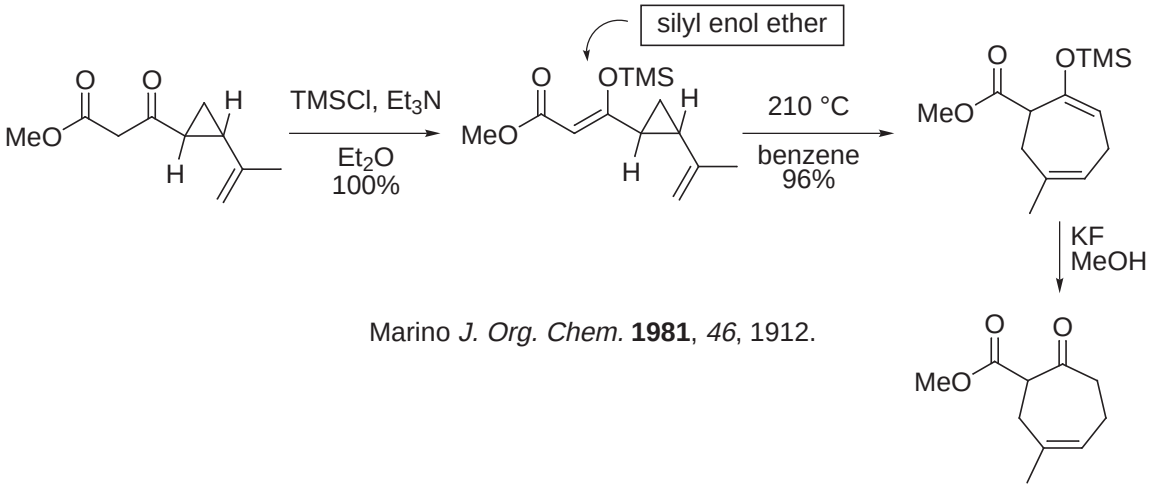
Comprehensive Org. Syn., Vol. 5, 971.
Org. React. **1992**, *41*, 1.

($2\sigma^s + 2\pi^s + 2\pi^s$)

- Mechanism:

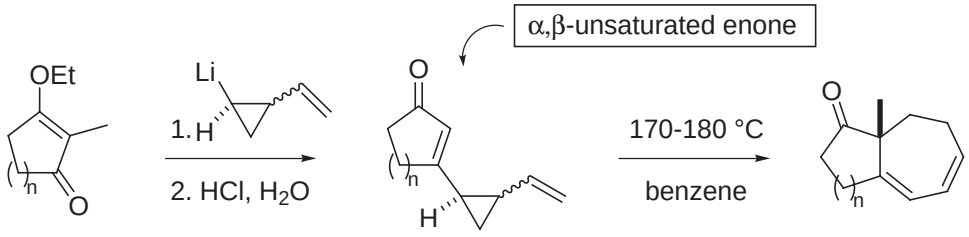


- Synthesis of functionalized 7-membered rings:



Marino *J. Org. Chem.* **1981**, *46*, 1912.

- Fused ring systems:



n = 1
n = 2

n = 1
n = 2

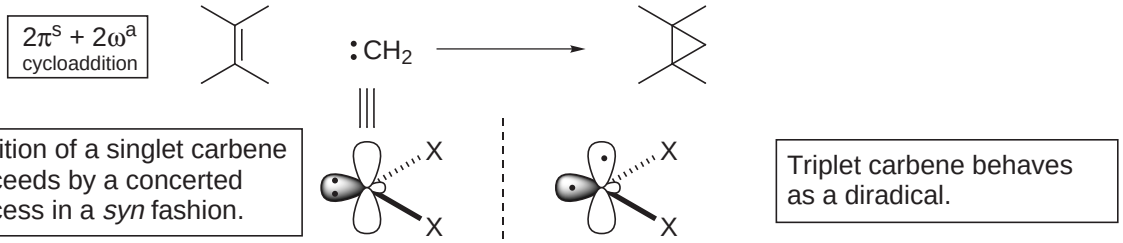
n = 1, 72%
n = 2, 74%

Wender *J. Org. Chem.* **1976**, *41,* 3490.

P. Carbene Cycloaddition to Alkenes

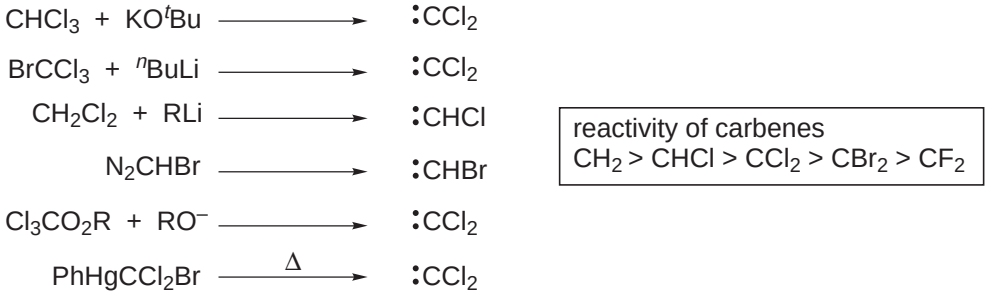
1. Halocabenes

Parman, Schweizer *Org. React.* **1963**, *13*, 55.
Moss *Acc. Chem. Res.* **1989**, *22*, 15.
Acc. Chem. Res. **1980**, *13,* 58.
Kostikov, Molchanov, Khlebnikov *Russ. Chem. Rev.* **1989**, *58*, 654.

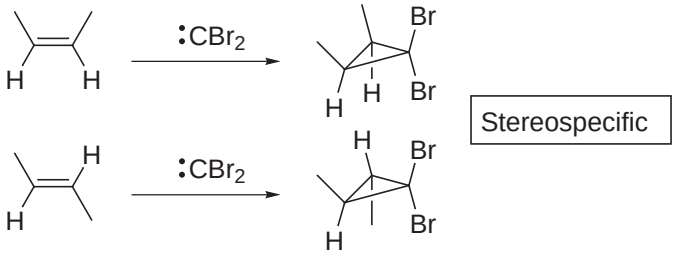


- Methods for generating halocarbenes:

For a comprehensive list see: Kirmse *Carbene Chemistry,* 1971, 313.

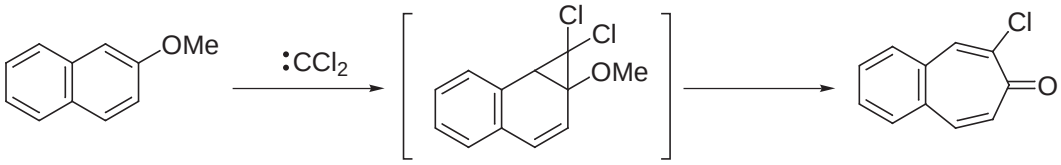


- Reaction with alkenes:

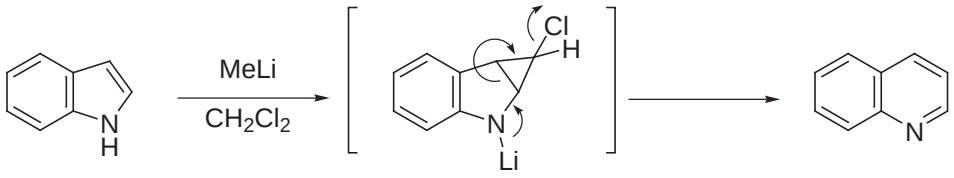


Doering *J. Am. Chem. Soc.* **1956**, *78*, 5447.

- Reaction with aromatic C=C bonds (cyclopropanation followed by rearrangement):



Parman, Schweizer *J. Am. Chem. Soc.* **1961**, *83*, 603.

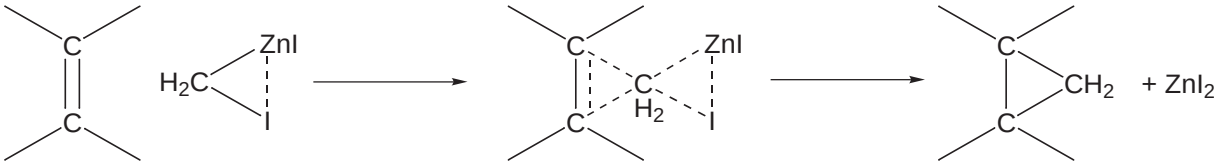


Closs, Schwartz *J. Org. Chem.* **1961**, *26*, 2609.

2. Simmons-Smith Reaction

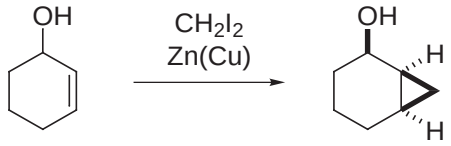
Simmons *Org. React.* **1973**, *20*, 1.
Simmons, Smith *J. Am. Chem. Soc.* **1958**, *80,* 5323.

- Mechanism:

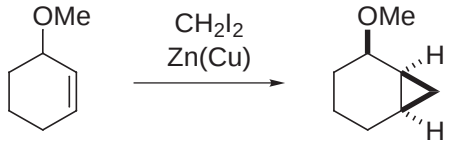


1) concerted mechanism likely (above)
2) reaction is stereospecifically *syn*
3) alkenes with higher alkyl substitution react faster
4) electron donating substituents accelerate reaction
i.e., enol ethers, enamines...

- Addition can be directed by a hydroxyl group or ether functionality:



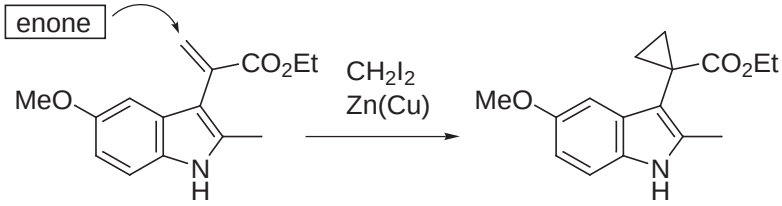
60%, 100% *cis*



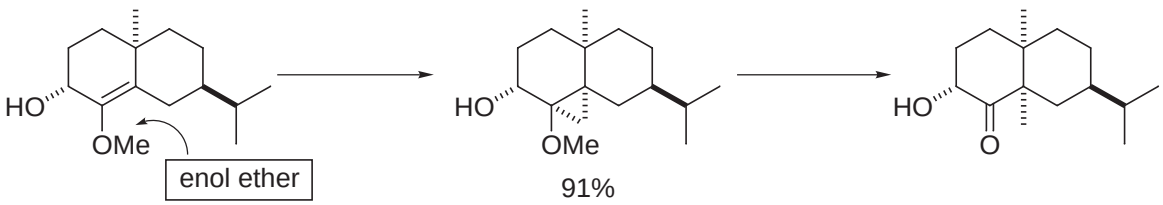
70%, 100% *cis*

Rickborn *J. Am. Chem. Soc.* **1968**, *90*, 6406.
J. Org. Chem. **1972**, *37*, 738.

- Examples:



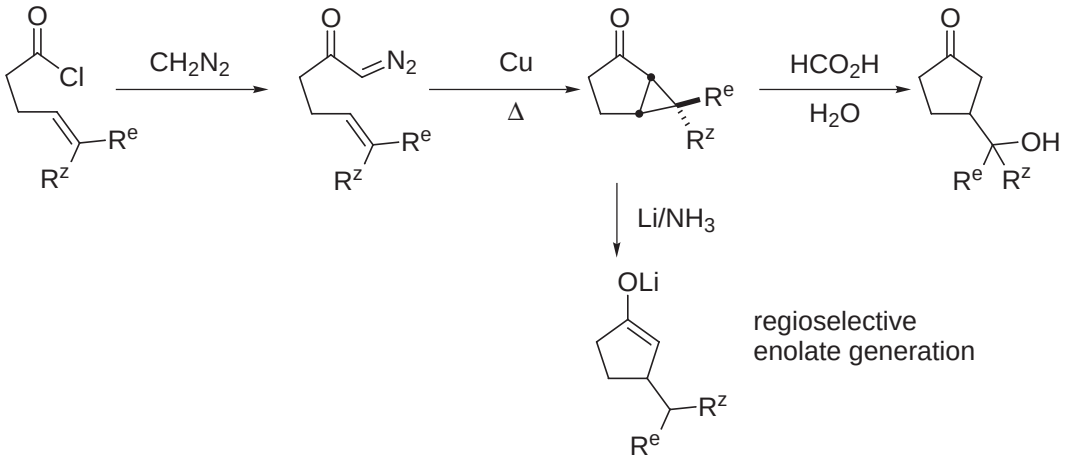
Shen *Chem. Abstr.* **1967**, *67*, 108559m.

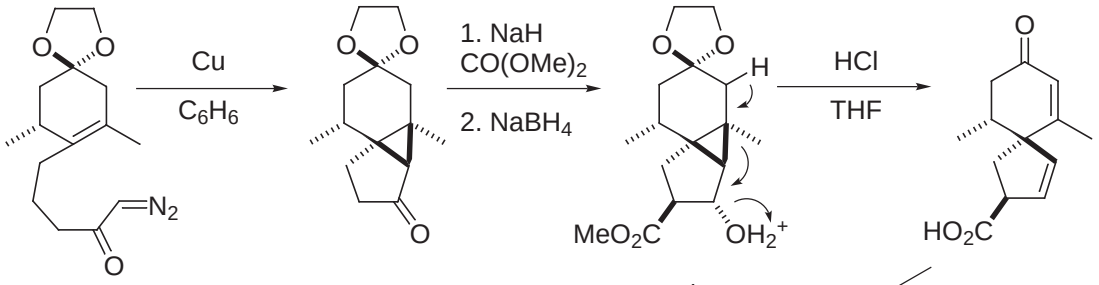


Wenkert, Berges *J. Am. Chem. Soc.* **1967**, *89*, 2507.

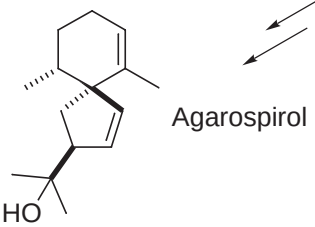
3. Diazocarbene Addition - Rearrangement

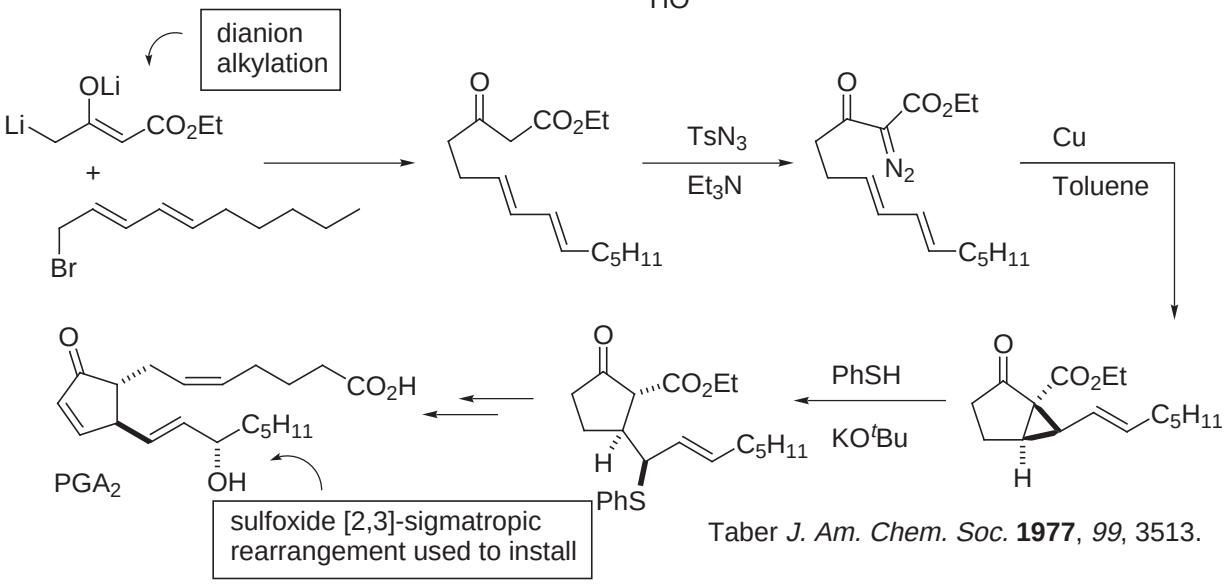
Review: Burke and Grieco *Org. React.* **1979**, *26*, 361.



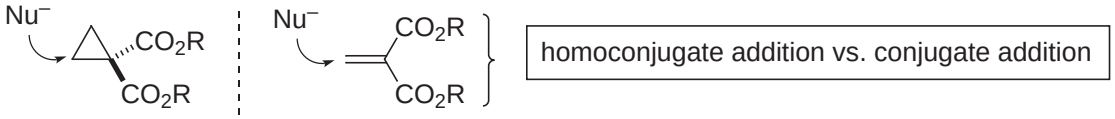


Delongchamps *Can. J. Chem.* **1970**, *48*, 3273.
Can. J. Chem. **1980**, *58*, 2460.





Taber *J. Am. Chem. Soc.* **1977**, *99*, 3513.



4. Metal-Carbene Cycloaddition Reactions

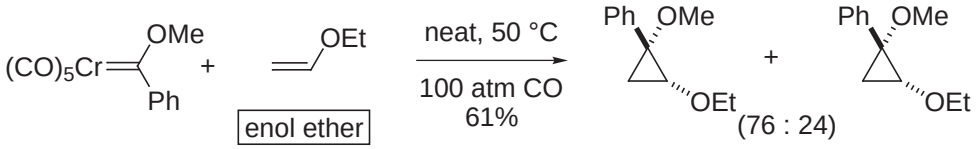
Comprehensive Org. Syn., Vol. 5, pp. 1065.

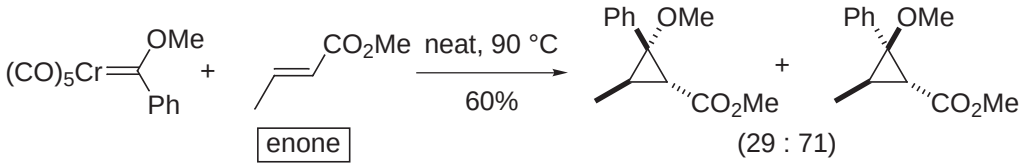
E. O. Fischer received the 1973 Nobel Prize in Chemistry for his work in organometallic chemistry with transition metal complexes including metallocenes and his stabilized carbene complexes.

- Three-membered ring [2 + 1]

Bookhart, Studabaker *Chem. Rev.* **1987**, *87*, 411.
Doyle *Chem. Rev.* **1986**, *86*, 919.

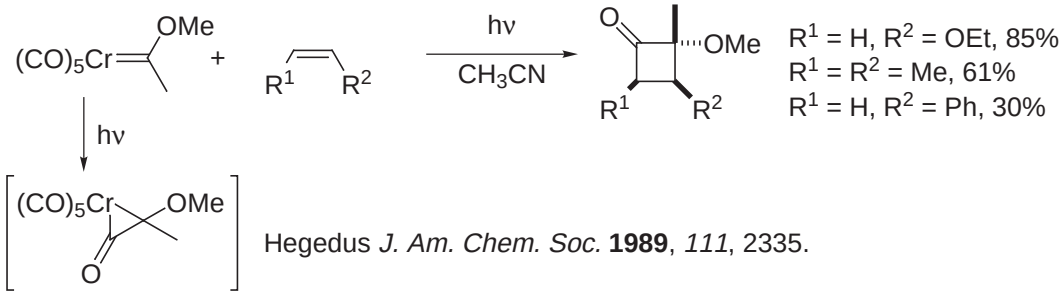
Reaction works well for electron-rich, electron-poor and unactivated C=C bonds.





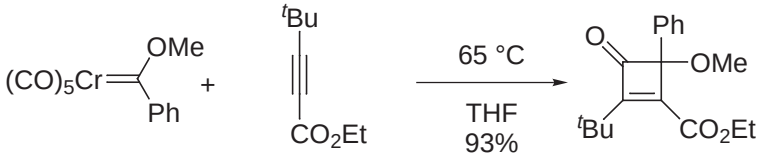
Fischer, Dötz *Chem. Ber.* **1972**, *105*, 3966.
Chem. Ber. **1972**, *105*, 1356.

- Four-membered rings [2 + 1 + 1]



Hegedus *J. Am. Chem. Soc.* **1989**, *111*, 2335.

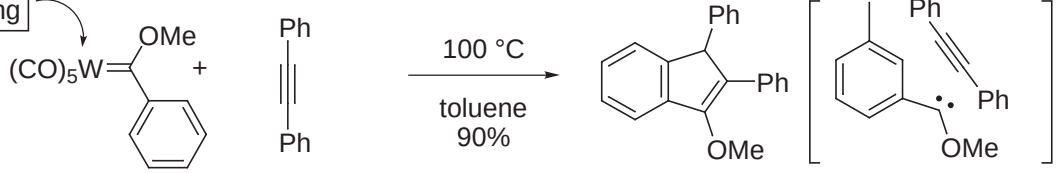
- Fischer carbene addition to alkynes typically leads to 6-membered ring , 4- and 5-membered rings form only under special circumstances.



4-membered ring formation is a result of the large *t*butyl group.

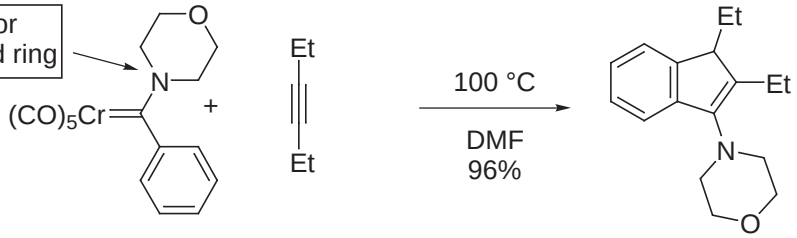
Yamashita *Tetrahedron Lett.* **1986**, *27*, 3471.

Cr leads to 6-membered ring



Foly *J. Am. Chem. Soc.* **1983**, *105*, 3064.

N required for 5-membered ring



Yamashita *Tetrahedron Lett.* **1986**, *27*, 5915.

- Six-membered rings [3 + 2 + 1] (Fischer carbene addition to alkynes)

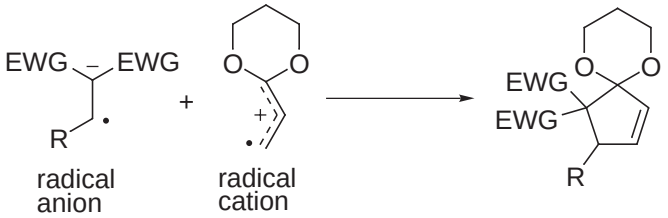
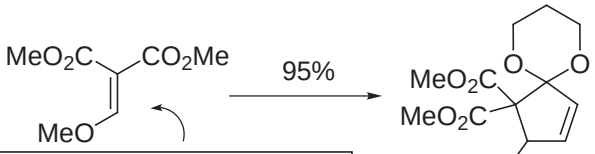
single e⁻ transfer

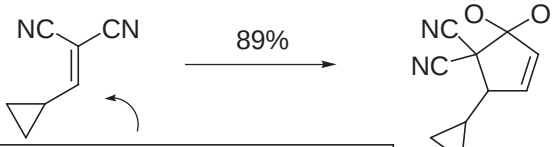


Note: For substrates that may react via this pathway (e⁻ transfer), [3 + 2] > [1 + 2], [4 + 2], or [3 + 4] cycloadditions

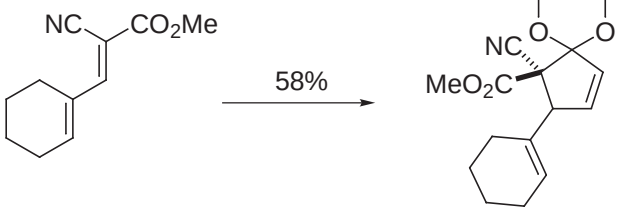
1. Solvent independent rate.
2. No addition-elimination or addition-rearrangement products.
3. No inhibition by free radical traps.
4. Putative carbene addition product (a cyclopropane ketene acetal) does not undergo vinylcyclopropane rearrangement to the product.
5. Little or no loss of olefin stereochemistry and this diastereospecific nature of the reaction increases, not decreases, in polar solvents.



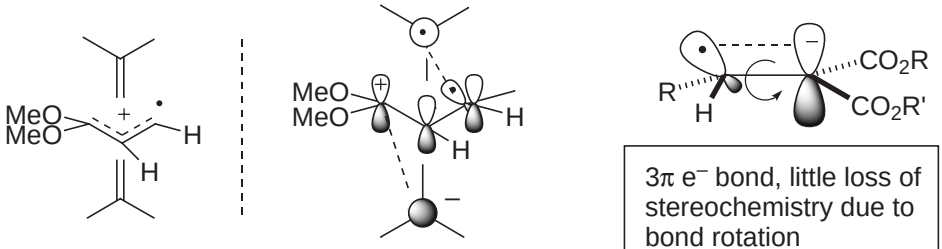
Unusual polarity that uniquely stabilized radical anion.



Cycloaddition faster than cyclopropylcarbinyl radical rearrangement.

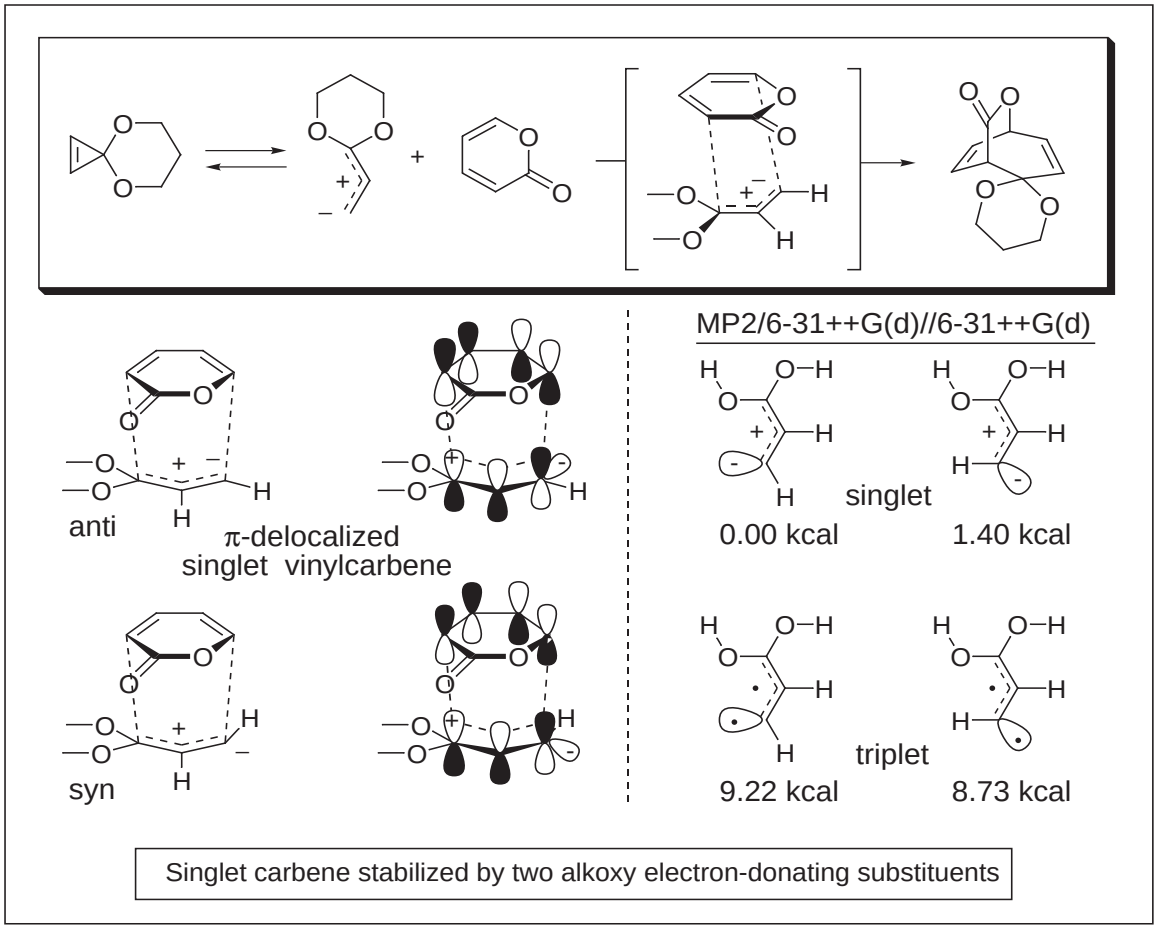


- ($2\pi^s + 2\pi^a$) Cycloaddition

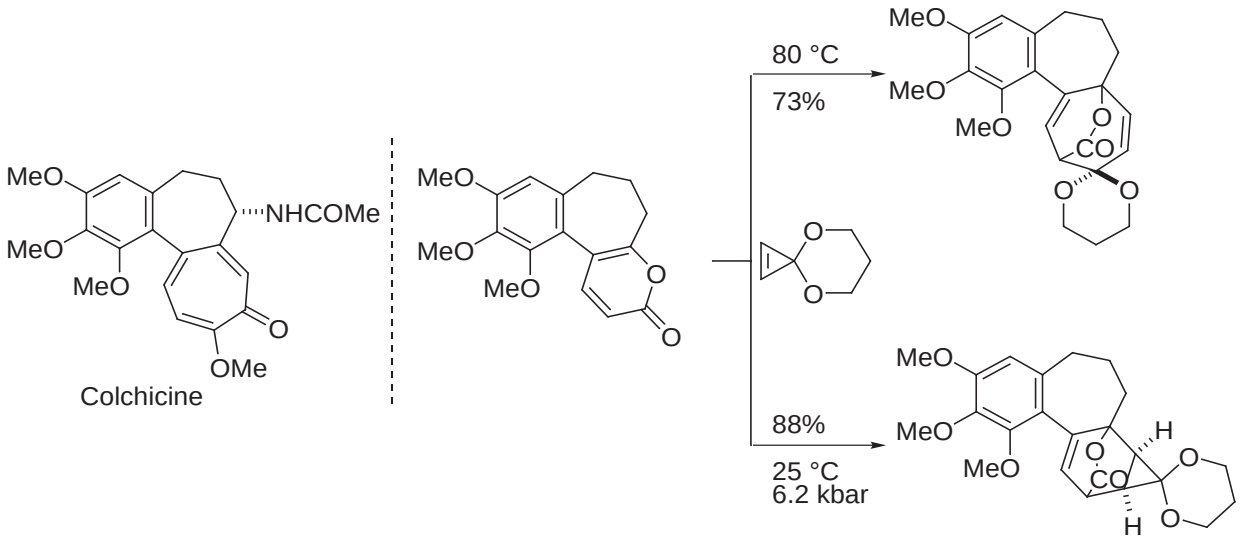


3π e⁻ bond, little loss of stereochemistry due to bond rotation

3. [4 + 3] Cycloaddition

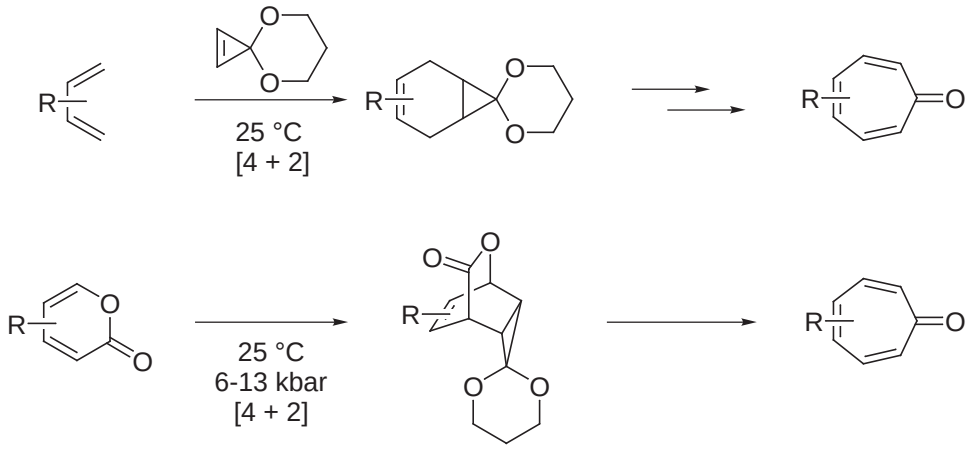


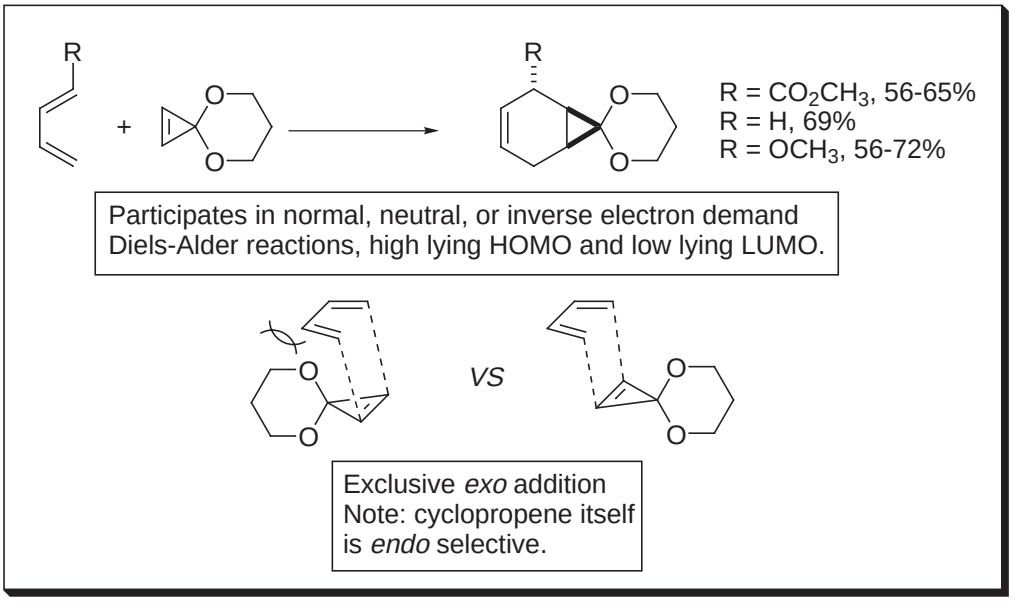
- $2\pi^s + 4\pi^s$ Cycloaddition or Diels-Alder but via a 2π three carbon dienophile.

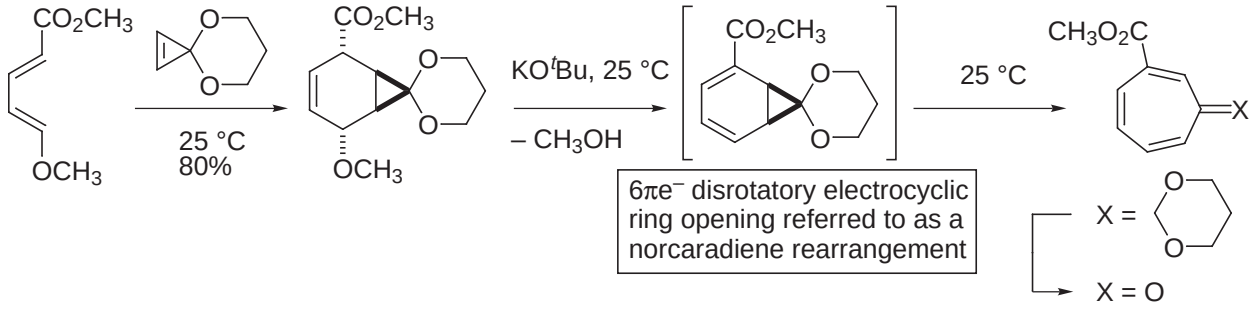


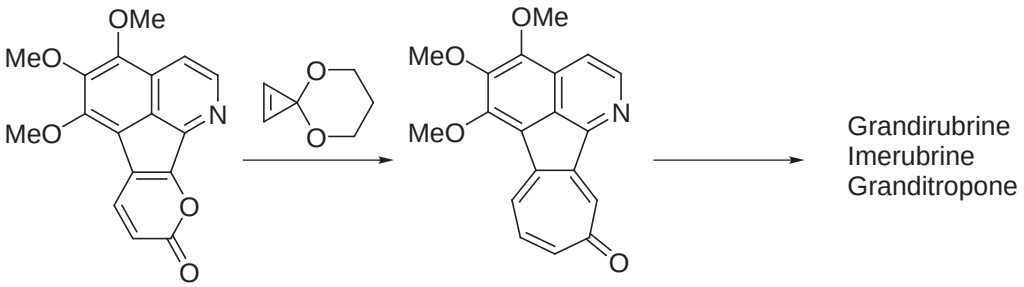
Boger *J. Am. Chem. Soc.* **1986**, *108*, 6713.

4. [4 + 2] Cycloaddition (standard Diels-Alder reaction)









Boger *J. Am. Chem. Soc.* **1995**, *117*, 12452.

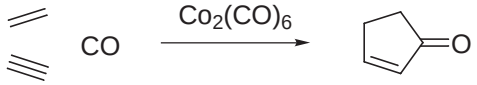
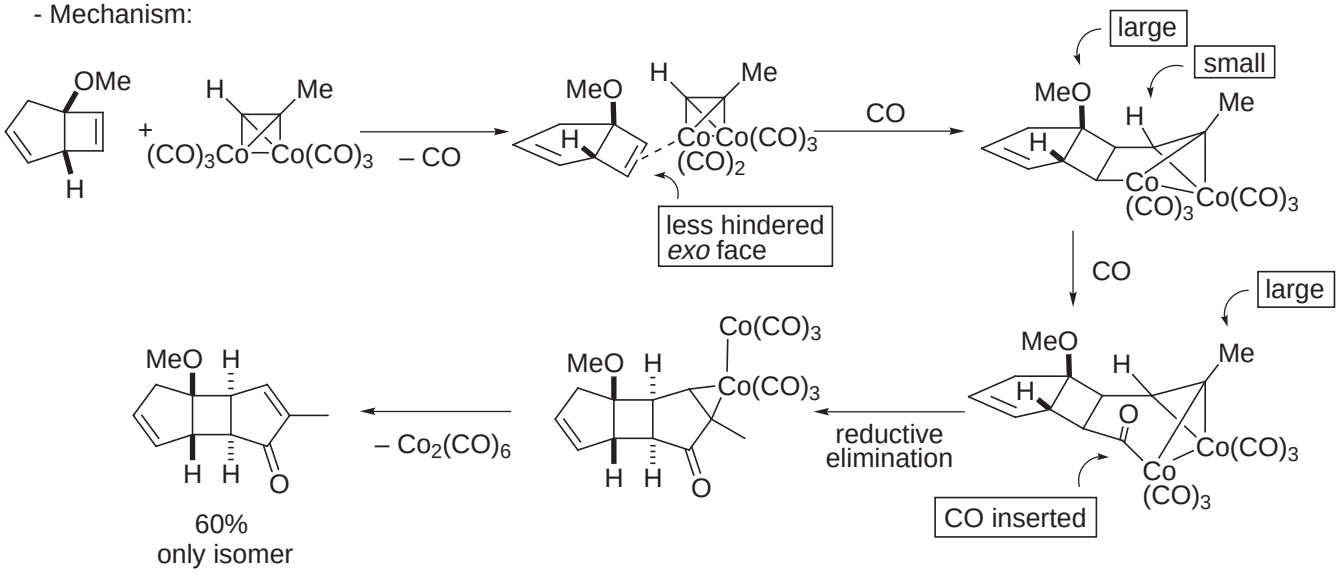
X. Pauson-Khand Reaction

[2 + 2 + 1]
Comprehensive Org. Syn., Vol. 5, pp. 1037-1064.
Org. React. **1991**, *40*, 1.
Pauson *Tetrahedron* **1978**, *41*, 5855.
Schore *Chem. Rev.* **1988**, *88*, 1081.
First detailed study: Khand *J. Chem. Soc., Perkin Trans. 1* **1973**, 977.



- Mechanism:



1. Regio- and stereochemistry are controlled by steric factors.
2. Complexation of alkene and insertion into Co-C bond occurs from less hindered face.
3. Insertion of the alkene carbon bearing the largest allylic substituent to form the first C-C bond occurs at the alkyne carbon bearing the smallest substituent.
4. Subsequent CO insertion occurs next to the largest alkyne substituent.
5. Reductive elimination followed by decomplexation gives the final product.

- Intermolecular:

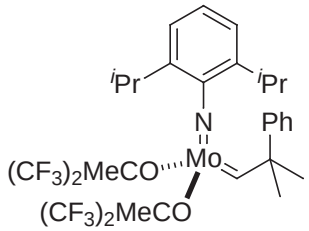
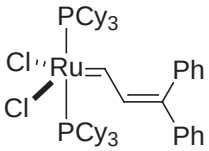
Sehrer *J. Sci. Ind. Res.* **1983**, *42*, 250.

- Defined Catalysts

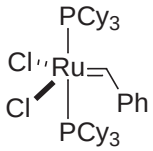
1. Early catalysts were poorly defined and incompatible with basic functionality.
2. Development of well-defined catalysts lead to high catalytic activity and compatibility with a wide variety of funtionalities.
3. Catalysts are based on variety of transition metals including: Mo, Ru, W, Re, Ti and Ta.
4. The mechanism appears the same for all transition metals.
5. The most widely used catalysts are:



1
Schrock



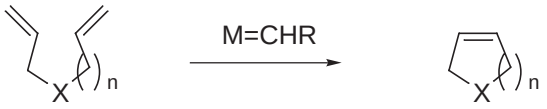
2
Grubbs



3
Grubbs

- Applications to organic synthesis

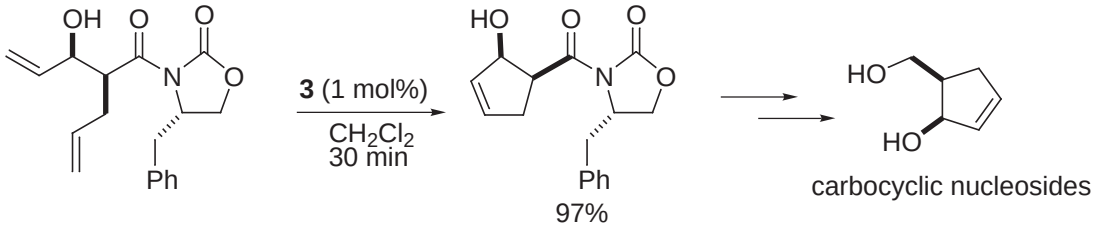
Ring closing metathesis is rapidly becoming one of the more powerful methods for preparing medium and large rings.
Modern use of ring closing metathesis traced back to:



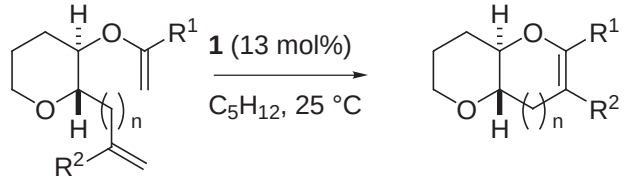
X = O, NR, CHR
n = 1, 2, 3

Grubbs, R. H.; Fu, G. C. *J. Am. Chem. Soc.* **1992**, *114*, 5426, 7324.
J. Am. Chem. Soc. **1993**, *115*, 3800.

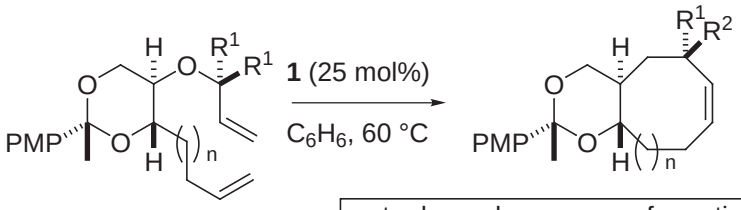
Recent examples:



Crimmins *J. Org. Chem.* **1996**, *61*, 4192.
Jacobsen *J. Org. Chem.* **1996**, *61*, 7963.



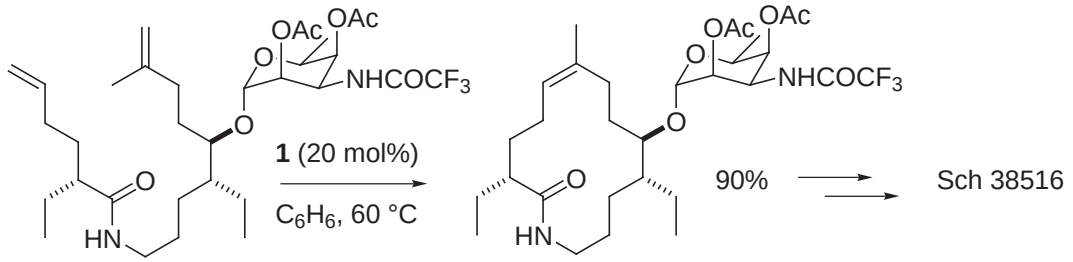
R^1 = H, n = 1, 2 >90%
R^1 = Et, n = 1, 2 42-73%



n	R^1	R^2	conc(M)	Yield
1	H	Et	0.008	97%
2	H	Et	0.003	86%
2	Et	H	0.003	14%
2	H	H	0.003	58%

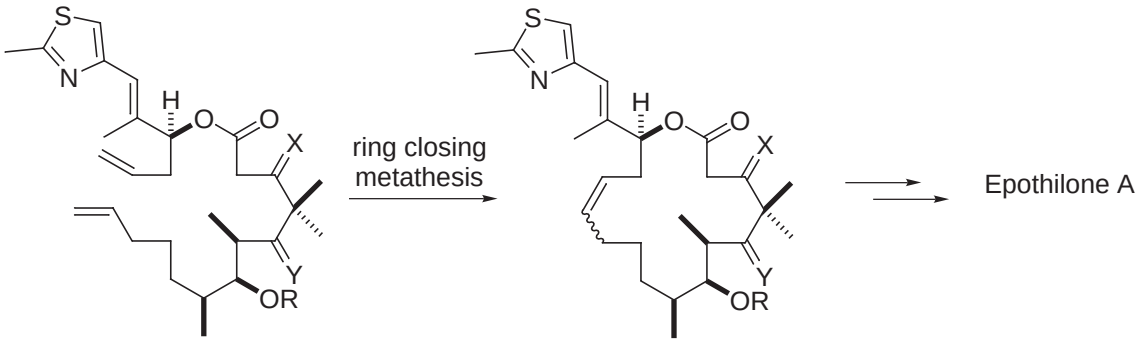
note dependence on conformation between two diastereomers.

Clark, Kettle *Tetrahedron Lett.* **1997**, *38*, 123 and 127.



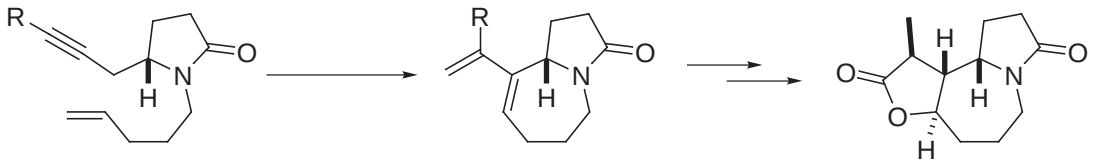
Hoveyda *J. Am. Chem. Soc.* **1995**, *117*, 2943.
J. Am. Chem. Soc. **1996**, *118*, 10926.

- Danishefsky, Nicolaou and Schinzer have all prepared Epothilone A using ring closing metathesis as the key cyclization step.



Danishefsky *J. Am. Chem. Soc.* **1997**, *119*, 2733.
Nicolaou *Angew. Chem., Int. Ed. Eng.* **1997**, *36*, 166.
Schinzer *Angew. Chem., Int. Ed. Eng.* **1997**, *36*, 523.

- Application to ring closing metathesis of enynes:

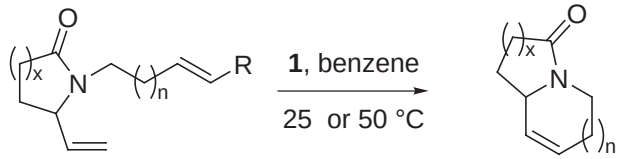


R = Me: **2** (5 mol%), C_6H_6, 50 °C, 73%
R = CO_2Me: **3** (4 mol%), CH_2Cl_2, 25 °C, 87%

(–)-Stemoamide

Kinoshita, Mori *J. Org. Chem.* **1996**, *61*, 8356.

- Application to the synthesis of fused nitrogen heterocycles:



a) x = 1
b) x = 2

a) x = 1
b) x = 2

n = 0, R = Me	a (68%)
n = 1, R = H	a (92%); b (91%)
n = 2, R = H	a (81%); b (84%)
n = 3, R = H	a (47%); b (50%)

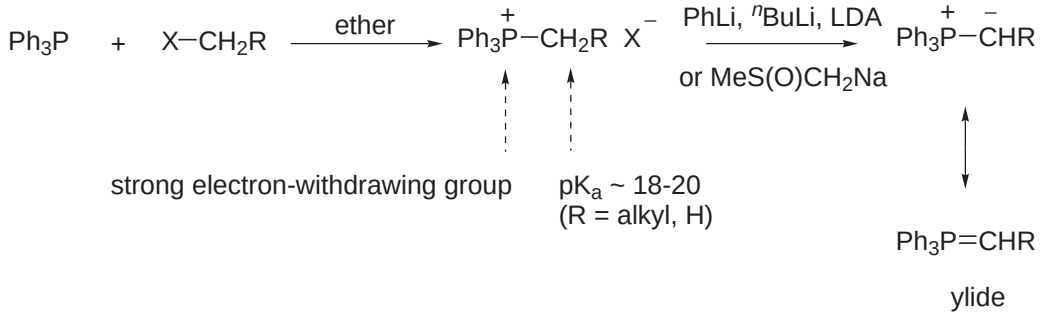
XI. Olefin Synthesis

A. Wittig Reaction

G. Wittig received the 1979 Nobel Prize in Chemistry for "many significant contributions to Organic Chemistry" which included not only the Wittig reaction, but also PhLi prepared by metal-halogen exchange, benzyne, and the Wittig rearrangement.

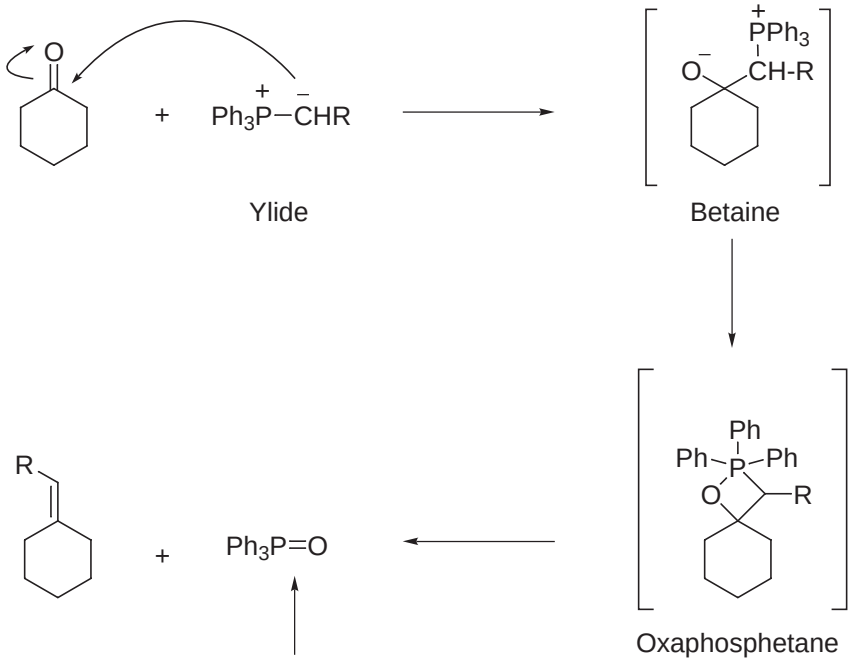
Reviews:
Comprehensive Org. Syn., Vol. 1, 755.
Org. React. **1965**, *14*, 270.
Angew. Chem., Int. Ed. Eng. **1964**, *3*, 250.
Top. Stereochem. **1970**, *5*, 1.
Pure. Appl. Chem. **1979**, *51*, 515.
Chem. Rev. **1989**, *89*, 863.

1. Formation of Ylides



- Unstabilized ylides are sensitive to H_2O, O_2

2. Reaction of Ylides with Ketones



Strong bond formation is part of the driving force for the collapse of the oxaphosphetane.

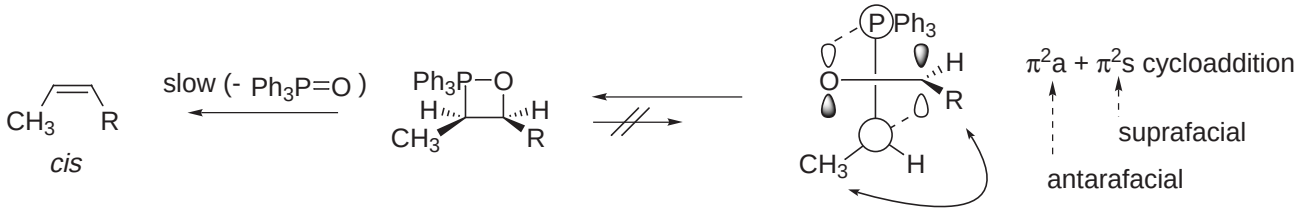
Wittig and Schöllkopf *Chem. Ber.* **1954**, *87*, 1318.

3. Mechanism and Stereoselectivity of the Wittig Reaction

cis olefin from nonstabilized ylides

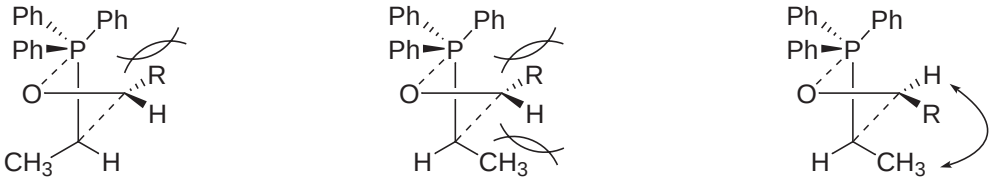
- Stereoselectivity increases as the size of the R group increases.

- Accepted mechanism today: irreversible and concerted [2 + 2] cycloaddition.



Orientation such that the R groups on the aldehyde and on the ylide are as far apart as possible.

- The three alternative [2 + 2] cycloaddition transition states suffer destabilizing steric interactions:



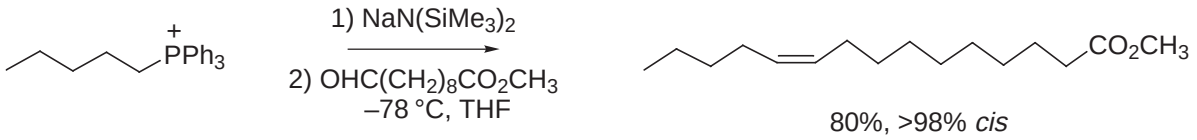
Not bad, probably gives rise to *trans* product

- So, the mechanism involves fast, irreversible [2 + 2] cycloaddition (usually occurs at –78 °C) followed by slow decomposition of oxaphosphetane (frequently requires warming to 0-25 °C).

- Nonpolar solvents facilitate the initial addition.

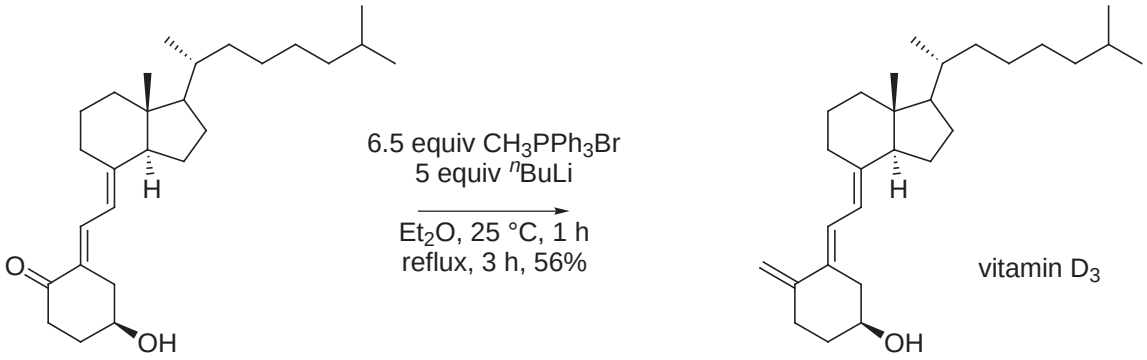
- Polar solvents facilitate the final elimination reaction.

4. Representative Examples



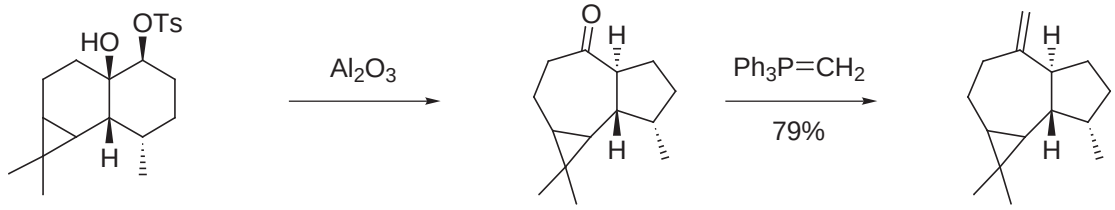
80%, >98% *cis*

Besterman *Chem. Ber*. **1976**, *109*, 1694.

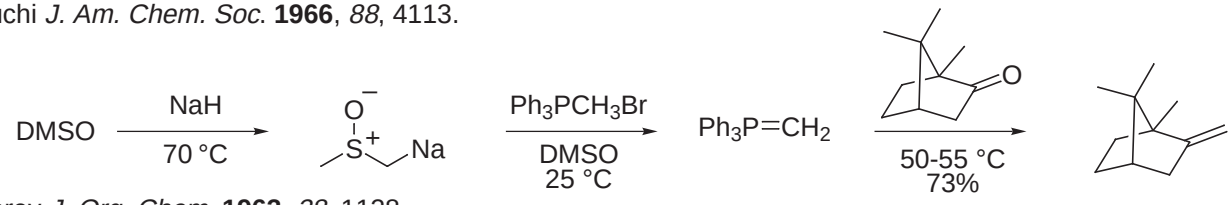


vitamin D_3

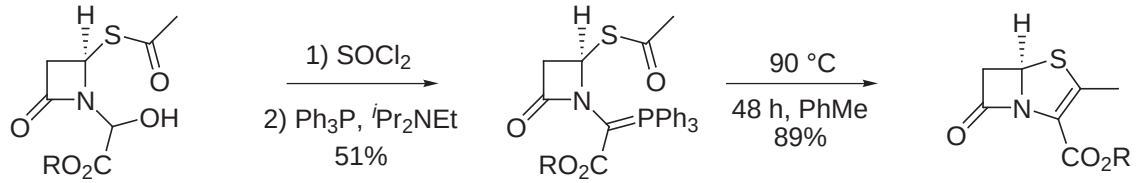
Inhoffen *Chem. Ber*. **1958**, *91*, 2309; *J. Am. Chem. Soc*. **1957**, *79*, 5029.



Büchi *J. Am. Chem. Soc*. **1966**, *88*, 4113.

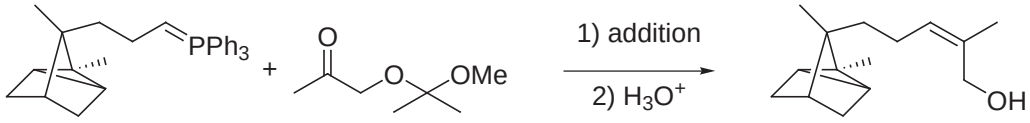


Corey *J. Org. Chem*. **1963**, *28*, 1128.



Woodward *J. Am. Chem. Soc*. **1979**, *101*, 6301.

- α-oxygenated substrates

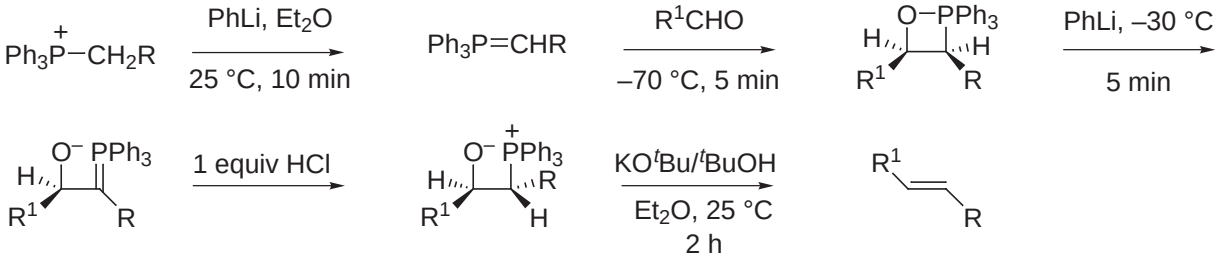


- trisubstituted *Z*-alkene

85%, >99% *Z*

Still *J. Org. Chem*. **1980**, *45*, 4260.

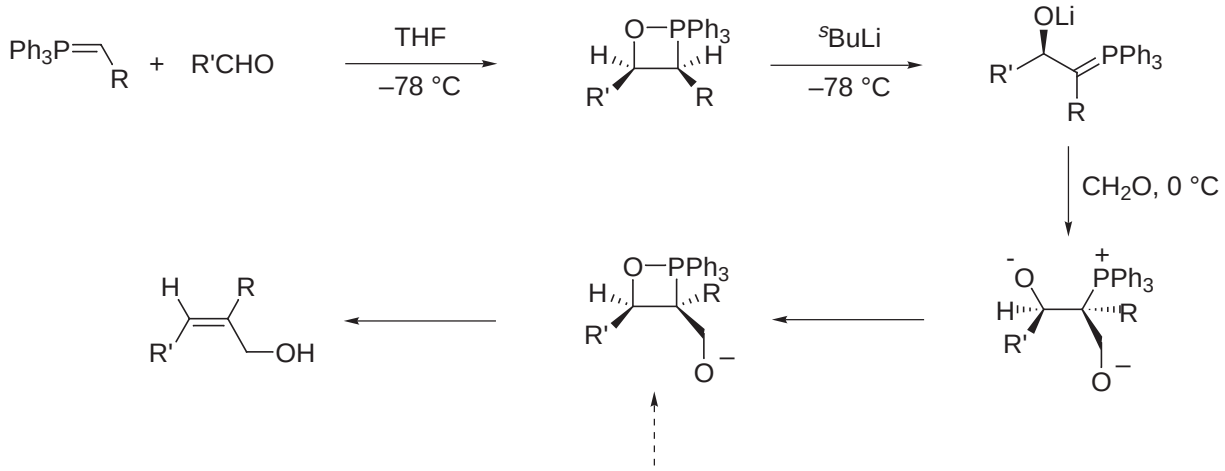
- Schlösser modification: allows the preparation of *trans* vs. *cis* olefins.



R	R^1	% yield	*trans:cis*
CH_3	C_5H_{11}	70	99:1
C_5H_{11}	CH_3	60	96:4
C_3H_7	C_3H_7	72	98:2
CH_3	Ph	69	99:1
C_2H_5	Ph	72	97:3

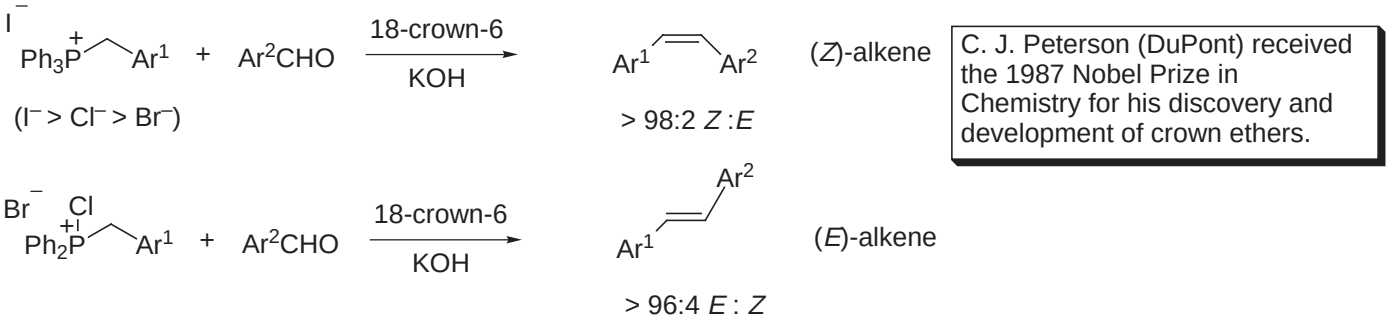
Schlösser *Angew. Chem., Int. Ed. Eng*. **1966**, *5*, 126.

- β-Oxido Phosphonium Ylide Reaction: adaptation of the Schlösser modification for the stereoselective preparation of trisubstituted allylic alcohols.



Only 2° alkoxide forms oxaphosphetane that eliminates to form the olefin.

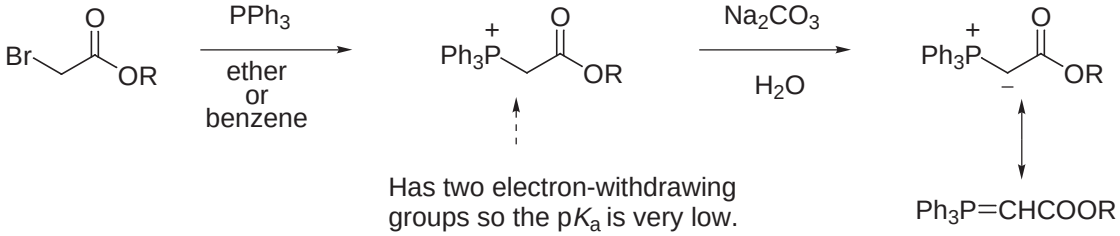
Corey, Katzenellenbogen and Posner *J. Am. Chem. Soc*. **1967**, *89*, 4245.
Corey and Yamamoto *J. Am. Chem. Soc*. **1970**, *92*, 226.
Corey and Yamamoto *J. Am. Chem. Soc*. **1970**, *92*, 6636.
Corey and Yamamoto *J. Am. Chem. Soc*. **1970**, *92*, 6637.



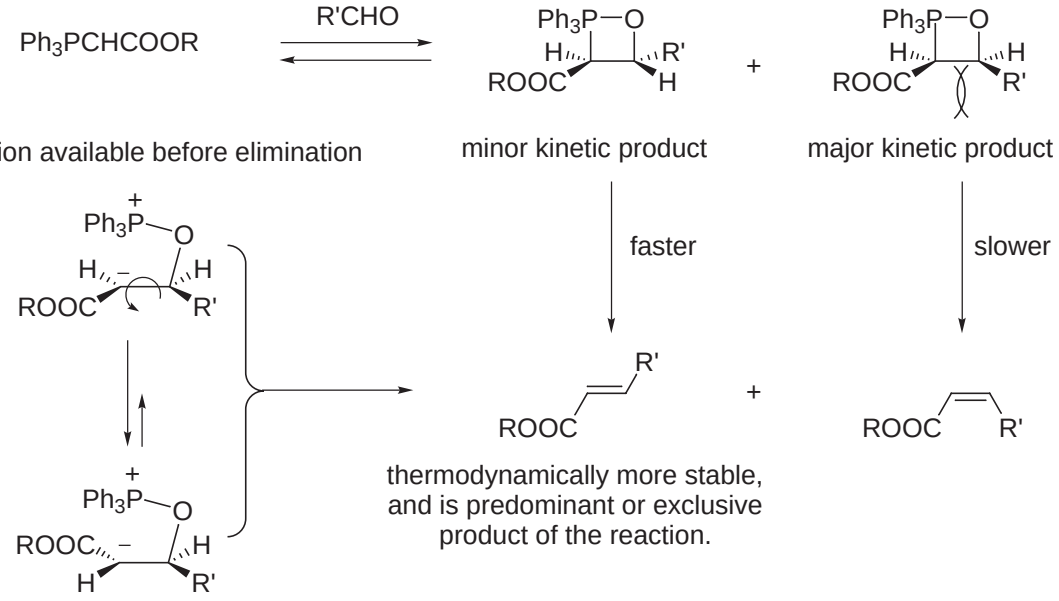
C. J. Peterson (DuPont) received the 1987 Nobel Prize in Chemistry for his discovery and development of crown ethers.

Chiappe *Tetrahedron Lett*. **1996**, *37*, 4225.

5. Stabilized Ylides

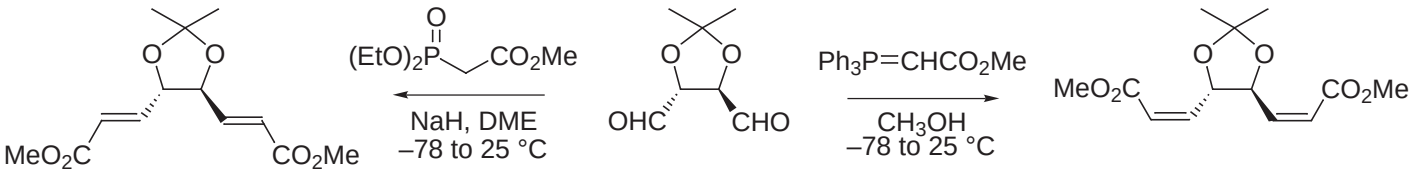


- Stabilized ylides are solid; stable to storage, not particularly sensitive to moisture, and can even be purified by chromatography.
- Because they are stabilized, they are much less reactive than alkyl ylides. They react well with aldehydes, but only slowly with ketones.
- The first step, involving the addition to the aldehyde, is slow and reversible with stabilized ylides.



- It is also possible that elimination occurs in a stepwise manner via stabilized zwitterionic intermediate that may simply afford the more stable product.

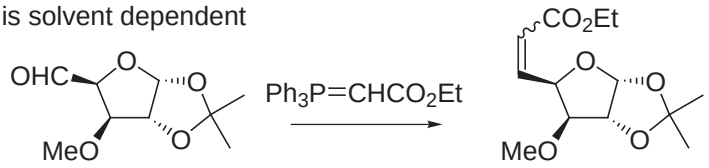
- α-oxygenated substrates
  - The exception to the generation of *E*-alkenes with stabilized ylides is their reaction with α-alkoxy aldehydes.



trans (*E*)-olefin *cis* (*Z*)-olefin!

Krief *Tetrahedron Lett.* **1988**, *29*, 1083.

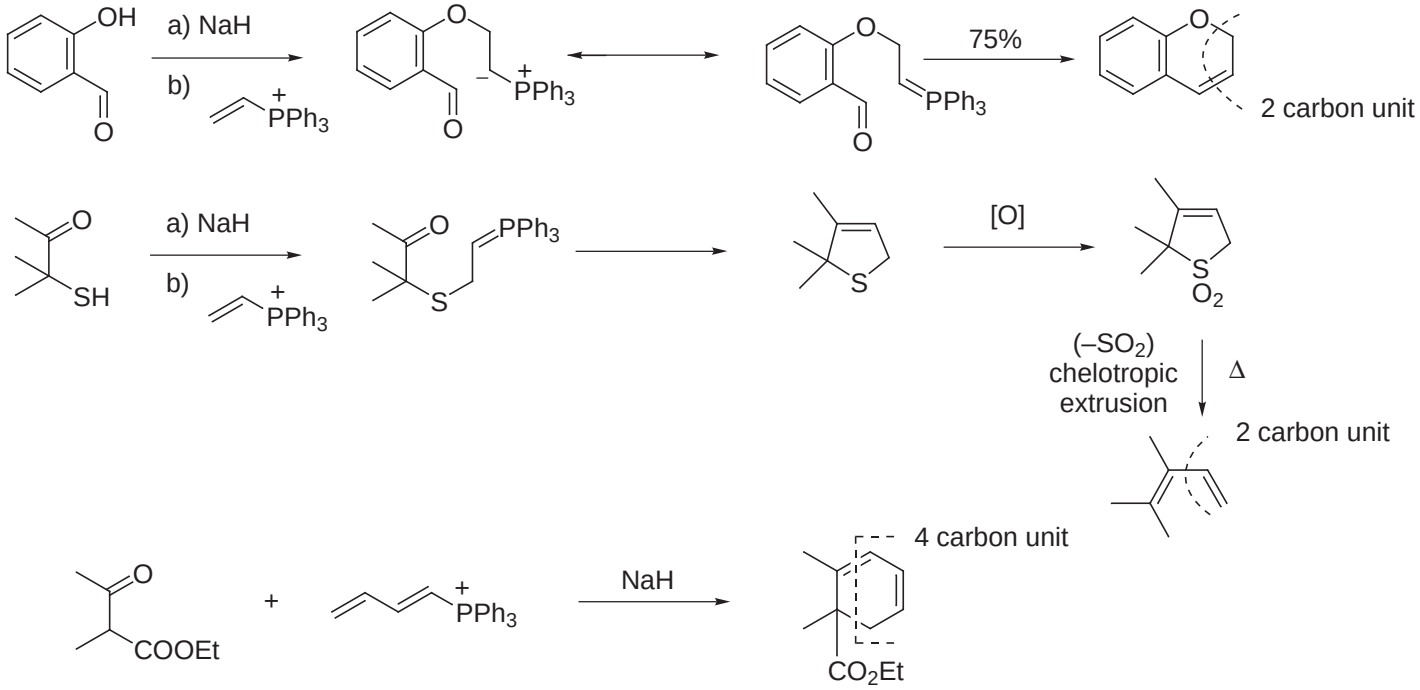
- And, this departure is solvent dependent



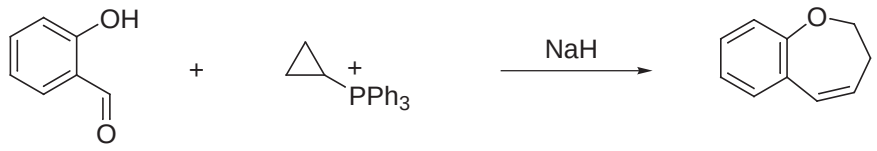
DMF	14 : 86	*Z* : *E* ← *trans*
$CHCl_3$	60 : 40	*Z* : *E*
MeOH	92 : 9	*Z* : *E* ← *cis*

Tronchet, Bentzle *Helv. Chim. Acta* **1979**, *62*, 2091.

6. Annulation Applications of the Wittig Reaction

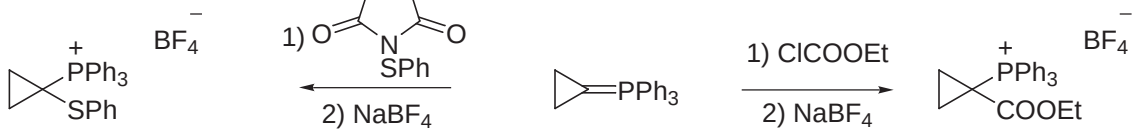


- Homoconjugate addition:



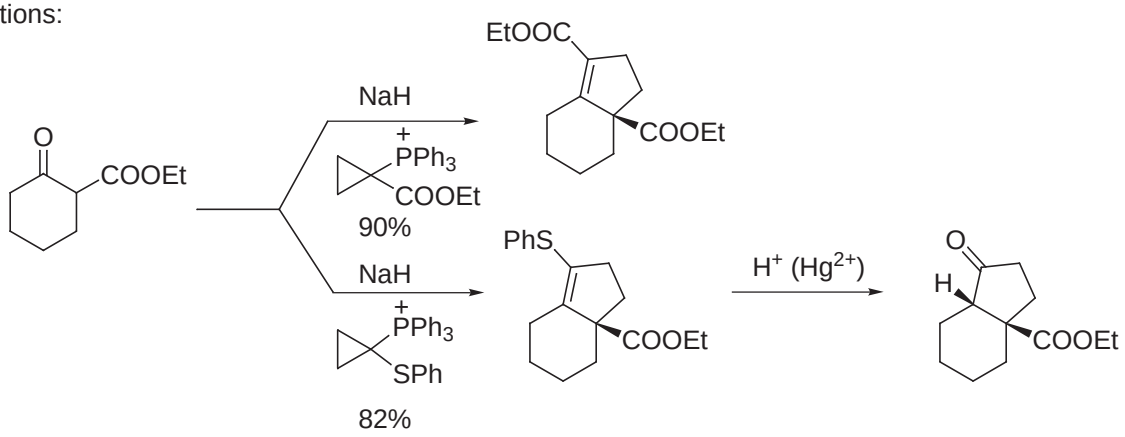
- Modest yields because one electron-withdrawing group is not sufficient to activate the cyclopropane ring to nucleophilic ring opening.

So:



Dauben *J. Am. Chem. Soc*. **1975**, *97*, 1622.

- Applications:

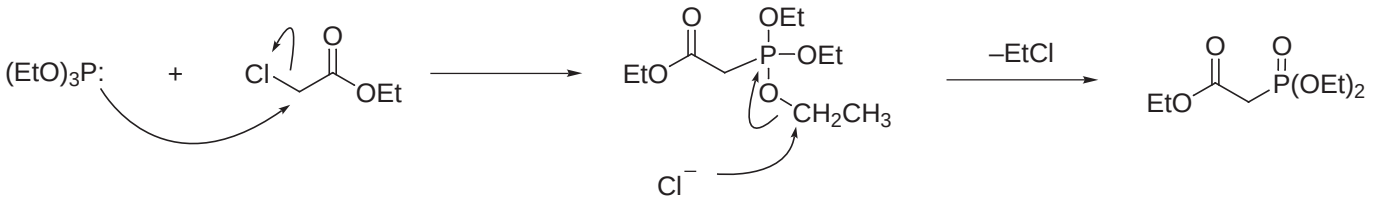


B. Wadsworth-Horner-Emmons Reaction

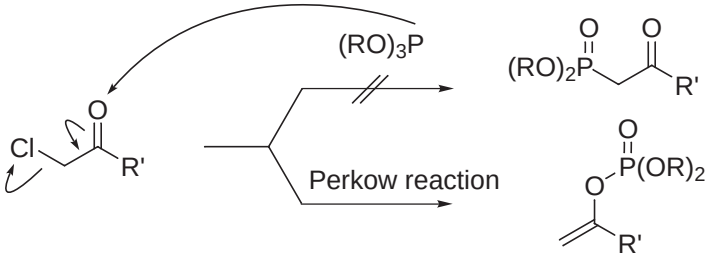
Horner *Chem. Ber.* **1958**, *91*, 61; **1959**, *92*, 2499.
Wadsworth, Emmons *J. Am. Chem. Soc.* **1961**, *83,* 1733.
Wadsworth, Emmons *J. Am. Chem. Soc.* **1966**, *88*, 5654.

Reviews: *Org. React.* **1977**, *25*, 73-253.
Comprehensive Org. Syn., Vol. 1, 761.

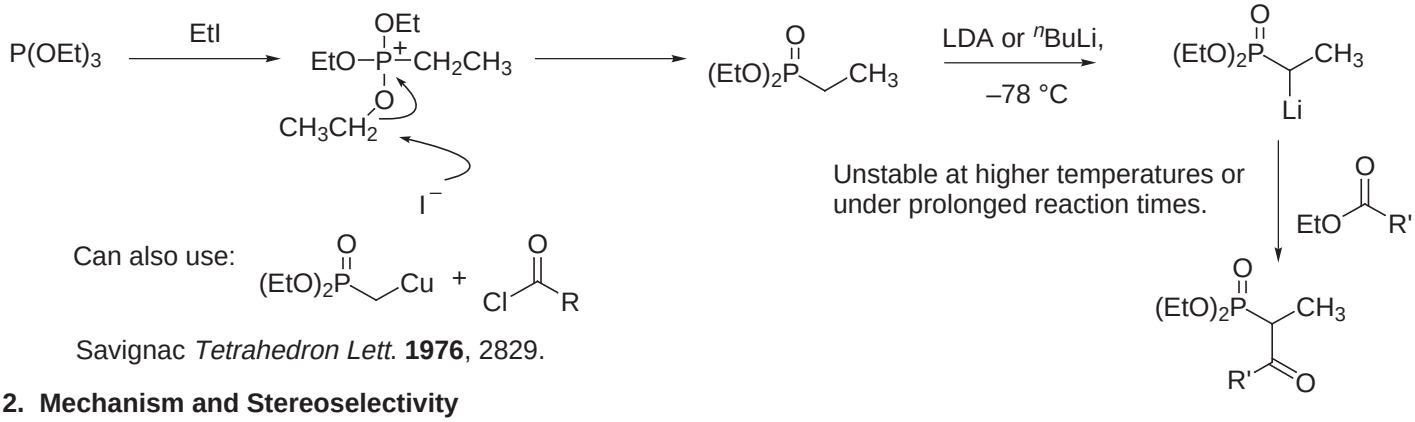
1. Arbuzov Reaction - Preparation of Phosphonate Esters



- The same approach to the preparation of β-ketophosphonates is not successful:



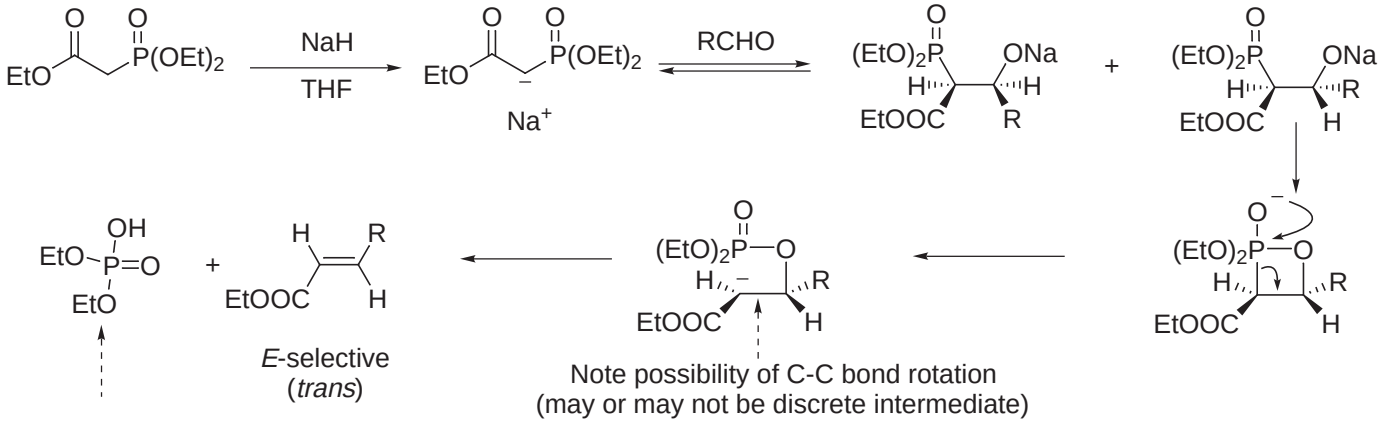
- But can use variation on Claisen conditions:



Can also use:

Savignac *Tetrahedron Lett.* **1976**, 2829.

2. Mechanism and Stereoselectivity



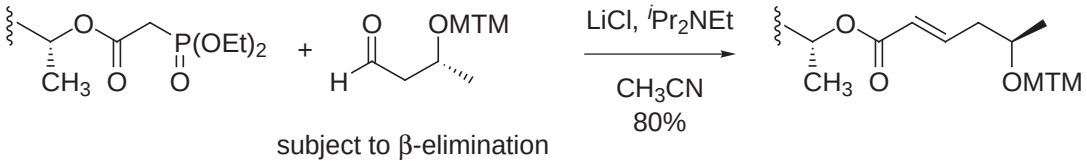
Water soluble (easily removed through aqueous workup)

Good reactions for: 
W = CN, COOR, C(O)R, CHO, SO_2Ph, Ph
But not W = alkyl, H

3. Modifications and Scope

- LiCl/tertiary amines (DBU, $^{i}Pr_2NEt$, Et_3N)

Masamune, Roush *Tetrahedron Lett.* **1984**, *25*, 2183.
Can substitute for conventional conditions and is especially good for base sensitive substrates (epimerization, elimination).



subject to β-elimination

Keck *J. Org. Chem.* **1989**, *54*, 896. (thioester was also stable to these conditions)

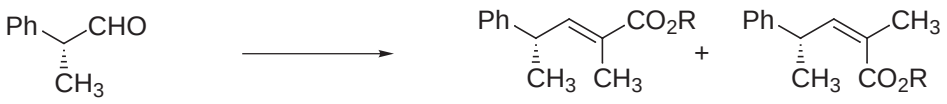
-Hindered phosphonates and hindered aldehydes increase *E*-selectivity (*trans*).

$Ph_3P{=}CHCO_2Et$, CH_2Cl_2, 0 °C	7 : 1	*E* : *Z*
$(^{i}PrO)_2POCH_2CO_2Et$, KO^{t}Bu, THF, –78 °C	95 : 5	*E* : *Z*
$(MeO)_2POCH_2CO_2Me$, KO^{t}Bu, THF, –78 °C	1 : 3	*E* : *Z*

Kishi *Tetrahedron* **1981**, *37*, 3873.

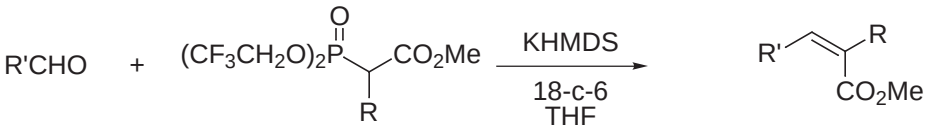
- The use of a nonhindered phosphonate, low temperatures, and a strongly dissociating base (KO^{t}Bu) can give increased or high *Z*-selectivity (*cis*).

- Coordinating countercations slow the rate of elimination relative to equilibration.



Stabilized Wittig reagent	$Ph_3P{=}C(Me)CO_2Et$, CH_2Cl_2, 25 °C	95	:	5
	$Ph_3P{=}C(Me)CO_2Et$, MeOH, 25 °C	85	:	15
Wadsworth-Horner-Emmons reagent	$(MeO)_2POCH(Me)CO_2Me$, KO^{t}Bu, THF, –78 °C	5	:	95
	$(MeO)_2POCH(Me)CO_2Et$, KO^{t}Bu, THF, –78 °C	10	:	90
	$(EtO)_2POCH(Me)CO_2Et$, KO^{t}Bu, THF, –78 °C	40	:	60
	$(^{i}PrO)_2POCH(Me)CO_2Et$, KO^{t}Bu, THF, –78 °C	90	:	10
	$(^{i}PrO)_2POCH(Me)CO_2{}^{i}Pr$, KO^{t}Bu, THF, –78 °C	95	:	5

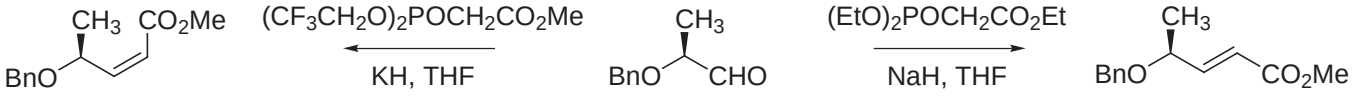
- Still-Gennari modification selective for *Z*-alkenes (*cis*):



R = H, Me

Z - selective
Z : *E* > 10 : 1

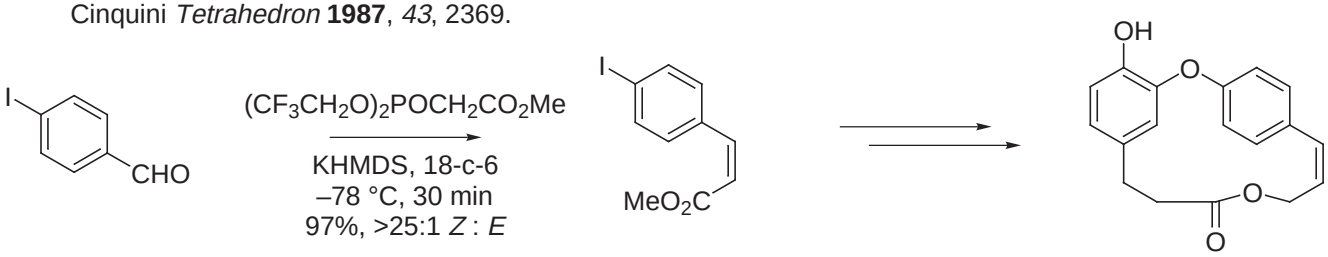
Still *Tetrahedron Lett.* **1983**, *24*, 4405.



84% 11 : 1 *Z* : *E*

83% 12 : 1 *E* : *Z*

Cinquini *Tetrahedron* **1987**, *43*, 2369.



Combretastatin D-2

Boger *J. Org. Chem*. **1991**, *56*, 4204.

Ando *J. Org. Chem*. **1997**, *62*, 1934.

Selected diarylphosphonates provide high (*Z*)-selectivity as well

C. Peterson Olefination

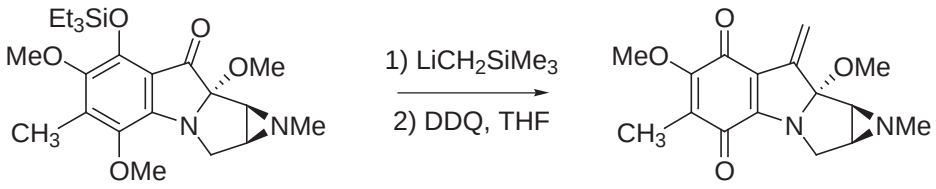
Peterson *J. Org. Chem*. **1968**, *33*, 781.

Reviews: *Org. React*. **1990**, *38*, 1.

1. Nonstabilized Peterson Reagents

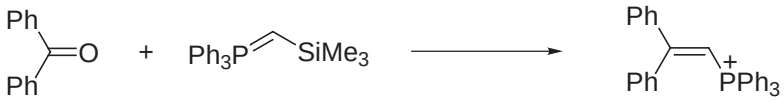
- Me_3SiCH_2Met, Met = Li, Mg, offer an alternative to Wittig or Tebbe procedures. They are more reactive and sterically less demanding than a Wittig reagent and the volatile byproduct (Me_3SiOH/ $Me_3SiOSiMe_3$) is simpler to remove than Ph_3PO. It does, however, require a second step to promote elimination of the β-hydroxysilane.

- Example



Danishefsky *J. Org. Chem*. **1988**, *53*, 3391.

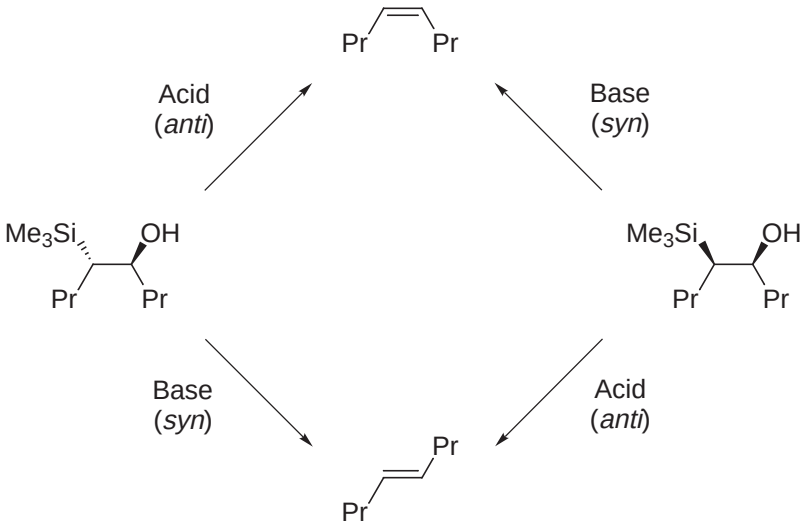
- TMS eliminates in preference to Ph_3P or $P(O)(OR)_2$:



Peterson. *J. Org. Chem*. **1968**, *33*, 780. Note: this is the origin of its discovery

- Modifications include: Me_3SiCH_2MgBr/ $TiCl_4$ (direct production of olefin), and Me_3SiCH_2Li/ $CeCl_3$ (enolizable ketones and aldehydes, while esters and acid chlorides give allylsilanes via addition 2x).

- The elimination is stereospecific: acid-promoted being *anti* and base-promoted being *syn*.

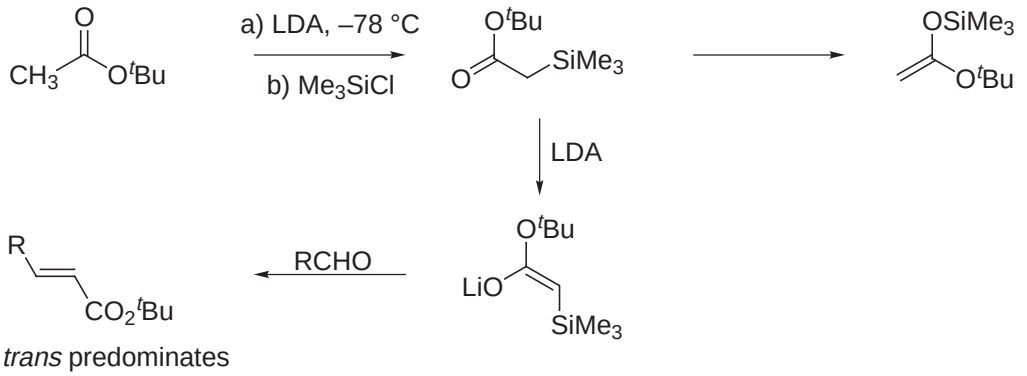


Hudrlik, Peterson *J. Am. Chem. Soc*. **1975**, *97*, 1464.

- Unstabilized Peterson reagents add to ketones and aldehydes irreversibly with little diastereoselectivity. Therefore, mixtures of *cis* and *trans* olefins are obtained and the reactions are not yet as useful as the Wittig reaction.

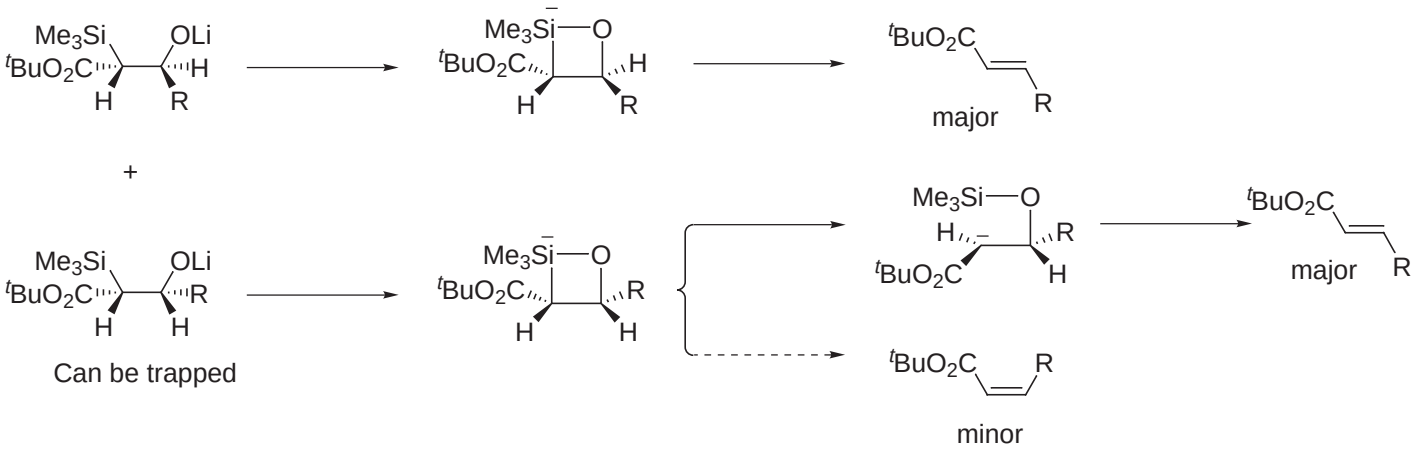
2. Stabilized Peterson Reagents

- The stabilized Peterson reagents give predominantly the most stable *trans* olefins (*E*) although this has been studied far less than the Wittig or Wadsworth-Horner-Emmons reactions. The origin of this diastereoselection has not been extensively explored with regard to enolate geometry, reversible/ irreversible addition, or mechanism of elimination. In this case, the elimination takes place under the reaction conditions.



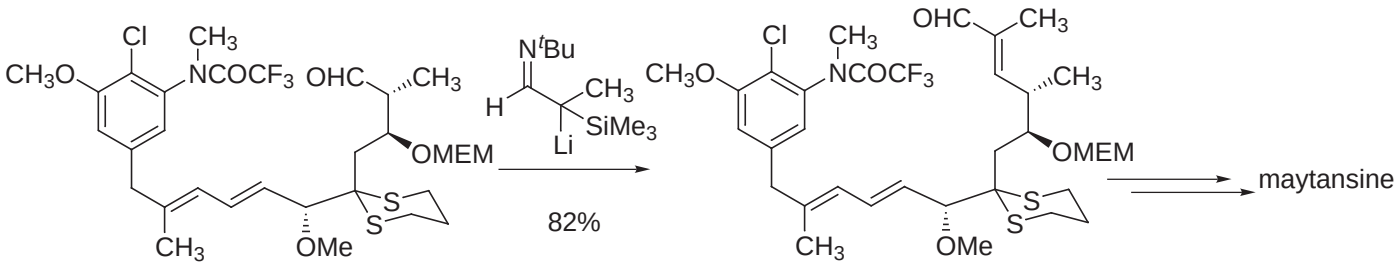
Rathke *Tetrahedron Lett.* **1974**, 1403.
Yamamota *J. Am. Chem. Soc.* **1974**, *96*, 1620.

- via:

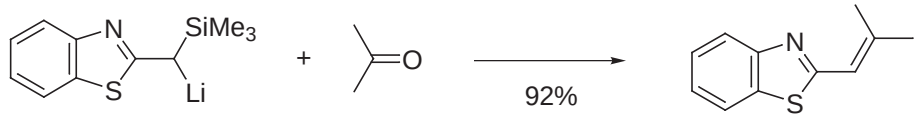


- Both single step and two-step elimination via an equilibration have been proposed.

- Additional examples:



Corey, Weigel, Chamberlin, Lipshutz *J. Am. Chem. Soc.* **1980**, *102*, 1439.
Corey, Enders, Bock *Tetrahedron Lett.* **1976**, 3 and 7.



Corey and Boger *Tetrahedron Lett.* **1978**, 5.

D. The Tebbe Reaction and Related Titanium-stabilized Methylenations

reviews: *Org. React.* **1993**, *43*, 1.
Comprehensive Org. Syn., Vol. 1, 743.

- The Wittig, Wadsworth-Horner-Emmons, and Peterson olefination do not convert esters or amides to the corresponding olefin, but rather fail to react or result in the cleavage of the ester or amide bond.

- Schrock discovered that Ta and Nb *tert*-butyl alkylidene complexes behave analogous to phosphorous ylides and, notably, react with esters and amides to provide the corresponding ^{t}butylalkenes.

Schrock *J. Am. Chem. Soc.* **1976**, *98*, 5399.

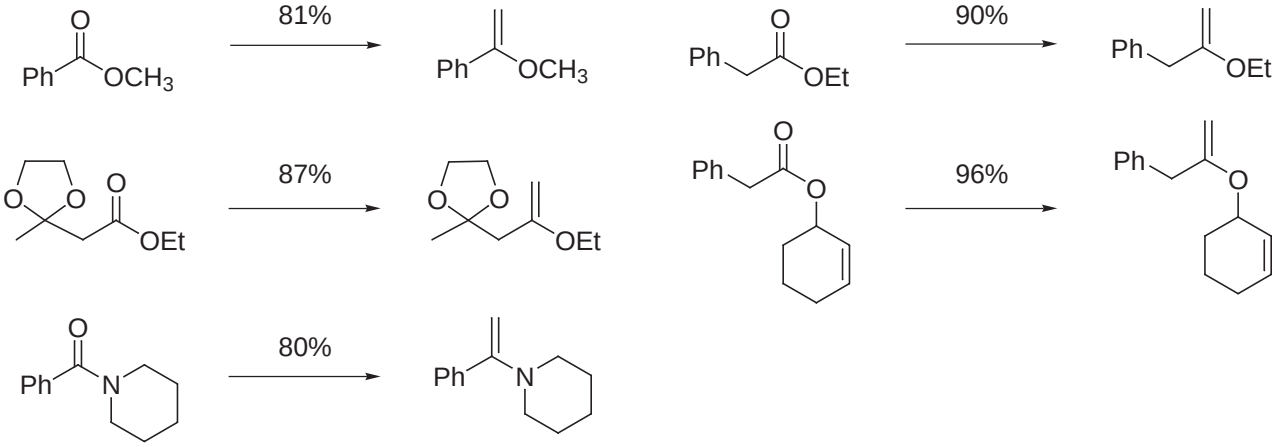
- The Tebbe reagent was introduced in 1978 and was shown to react with aldehydes, ketones, esters, and lactones to produce the methylene derivatives.

X = H, R, OR, NR_2 Tebbe reagent

Tebbe *J. Am. Chem. Soc.* **1978**, *100*, 3611.

- Tolerates ketal and alkene derivatives.

Scope defined by Evans and Grubbs *J. Am. Chem. Soc.* **1980**, *102*, 3270.
Extended to tertiary amides by Pine *J. Org. Chem.* **1985**, *50*, 1212.



Use of Cp_2TiMe_2: Petasis *J. Am. Chem. Soc.* **1990**, *112*, 6392.

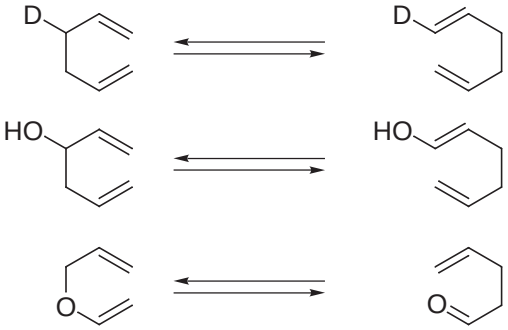
G. [3,3]-Sigmatropic Rearrangements

1. Claisen and Cope Rearrangement

Org. React. **1975**, *22*, 1.
Synthesis **1977**, 589.
Acc. Chem. Res. **1977**, *10*, 227.
Comprehensive Org. Syn., Vol. 5, pp. 785.



Cope Rearrangement

Oxy-Cope Rearrangement

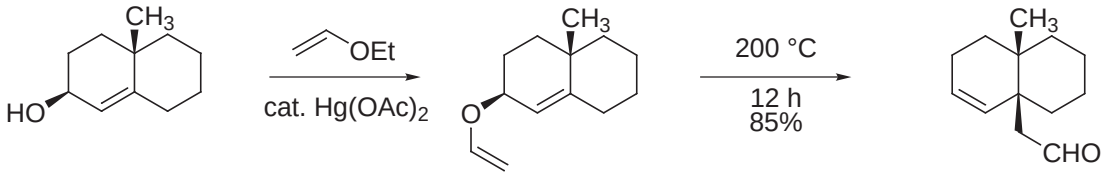
Claisen Rearrangement

Introduction of C=O is the driving force of the reaction

- Originally conducted on aryl allyl ethers.

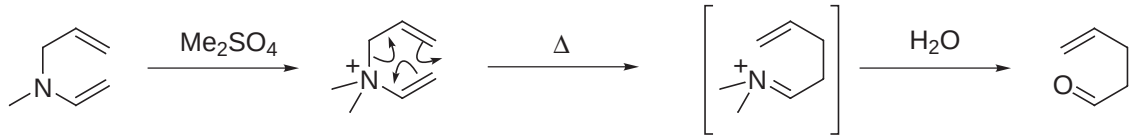
- Most useful variant established when extended to nonaromatic substrates.

- First example of an acyclic Claisen rearrangement:



Burgstahler *J. Am. Chem. Soc.* **1961**, *83*, 198.

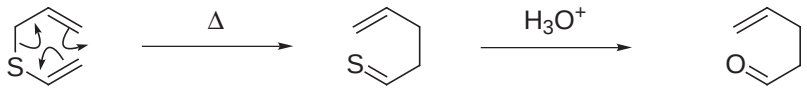
2. Amino-Claisen Rearrangement



- This reaction occurs best when nitrogen is converted to the ammonium salt.

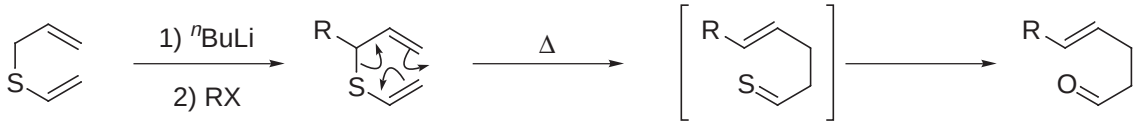
Gilbert *Tetrahedron Lett.* **1984**, *25*, 2303.
Stille *J. Org. Chem.* **1991**, *56*, 5578.

3. Thio-Claisen Rearrangement



- This reaction is often run with a reagent that will convert sulfur to oxygen following the reaction.

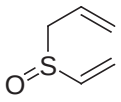
- An advantage of the thio-Claisen rearrangement is that the precursor can be deprotonated and alkylated.



trans C=C bond

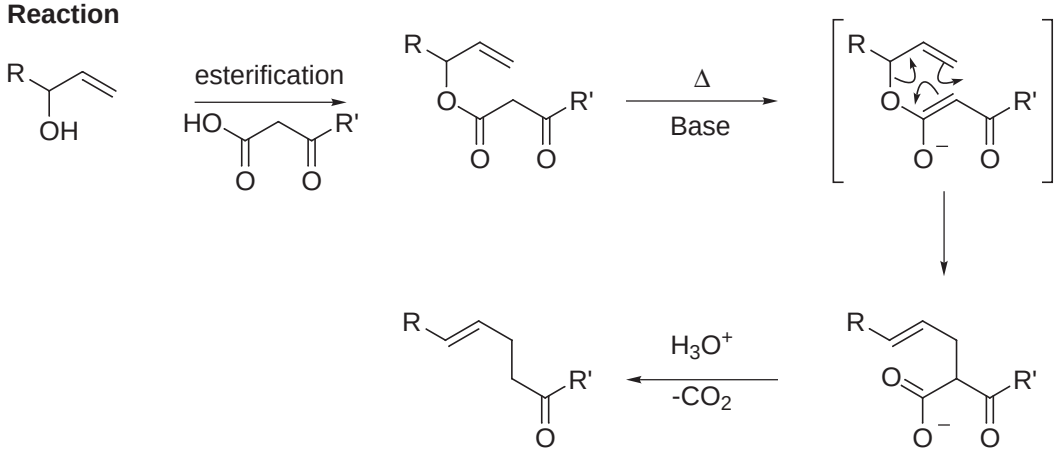
Corey *J. Am. Chem. Soc.* **1970**, *92*, 5522.
Yamamoto *J. Am. Chem. Soc.* **1973**, *95*, 2693 and 4446.

- Also can be conducted with the corresponding sulfoxide.



Block *J. Am. Chem. Soc.* **1985**, *107*, 6731.

4. The Carroll Reaction



Carroll *J. Chem. Soc.* **1940**, 704, 1266.

5. Corey Synthesis: *J. Am. Chem. Soc.* **1970**, *92*, 6635, 6636, 6637.

Lindlar Catalyst Alkyne Reduction
1,5-Hydrogen Migration
β-Oxido Ylide Reaction
Diimide Reduction

6. Johnson Synthesis: *J. Am. Chem. Soc.* **1970**, *92*, 4463.

3,3-Sigmatropic Rearrangements
- Claisen Reaction
- Cope Reaction
- Oxy-Cope Reaction

7. Stotter-Kondo Synthesis: *J. Am. Chem. Soc.* **1973**, *95*, 4444.
J. Chem. Soc., Chem. Commun. **1972**, 1311.

Dihydrothiopyran Strategy: Cyclic Precursors to Trisubstituted Olefins
- Stabilized Allylic Anions, Desulfurization (Benkeser Dissolving Metal Reduction)

Sulfur Ylides
- Cyclopropane Synthesis
- Epoxide Synthesis

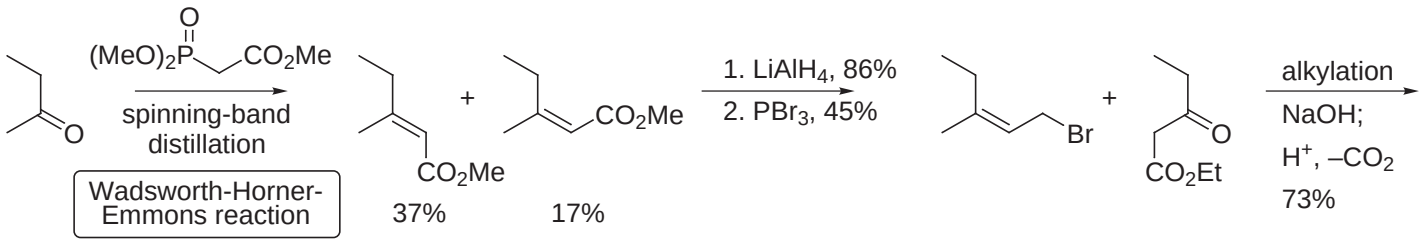
8. Still Synthesis: *Tetrahedron Lett.* **1979**, 593.

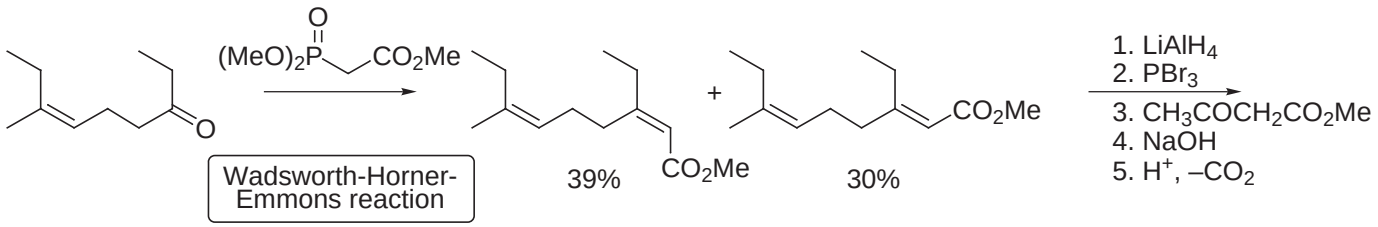
2,3-Sigmatropic Rearrangement

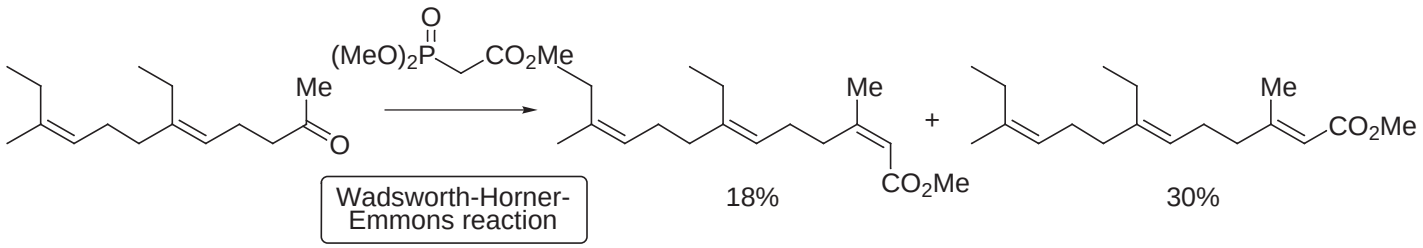
9. Other Syntheses:

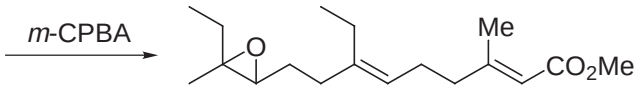
Beltsville Synthesis:	*J. Econ. Entomol.* **1968**, *61*, 866.
Mori Synthesis:	*Tetrahedron* **1969**, *25*, 1667.
MacKay Synthesis:	*J. Chem. Soc., Chem. Commun.* **1969**, 733.
Schering Synthesis:	*Angew. Chem., Int. Ed. Eng.* **1969**, *8*, 271. (Farnesol -> C-18 JH)
Zoecon Synthesis:	*J. Am. Chem. Soc.* **1970**, *92, 735.*
van Tamelen Synthesis:	*J. Am. Chem. Soc.* **1970**, *92, 737.*

1. Trost Synthesis: *J. Am. Chem. Soc.* **1967**, *89*, 5292. Wadsworth-Horner-Emmons Reaction





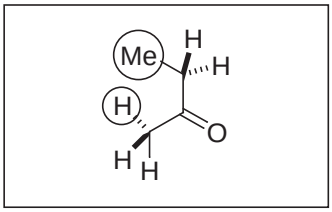




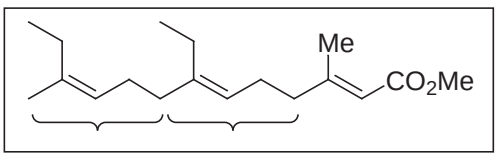
40% C-18 JH
10% internal epoxide
10% diepoxide

Relative Activity	
nat. C-18 JH	1
syn. C-18 JH	1
t-t-t (epoxide)	0.4
c-t-t (triene)	0.1
t-t-t (triene)	0.04
c-t-t (epoxide) ethyl ester	8

Synthesis was relatively non-stereospecific
- structural assignment
- structure-activity studies
- prevents adult development from pupa
- more potent analog found



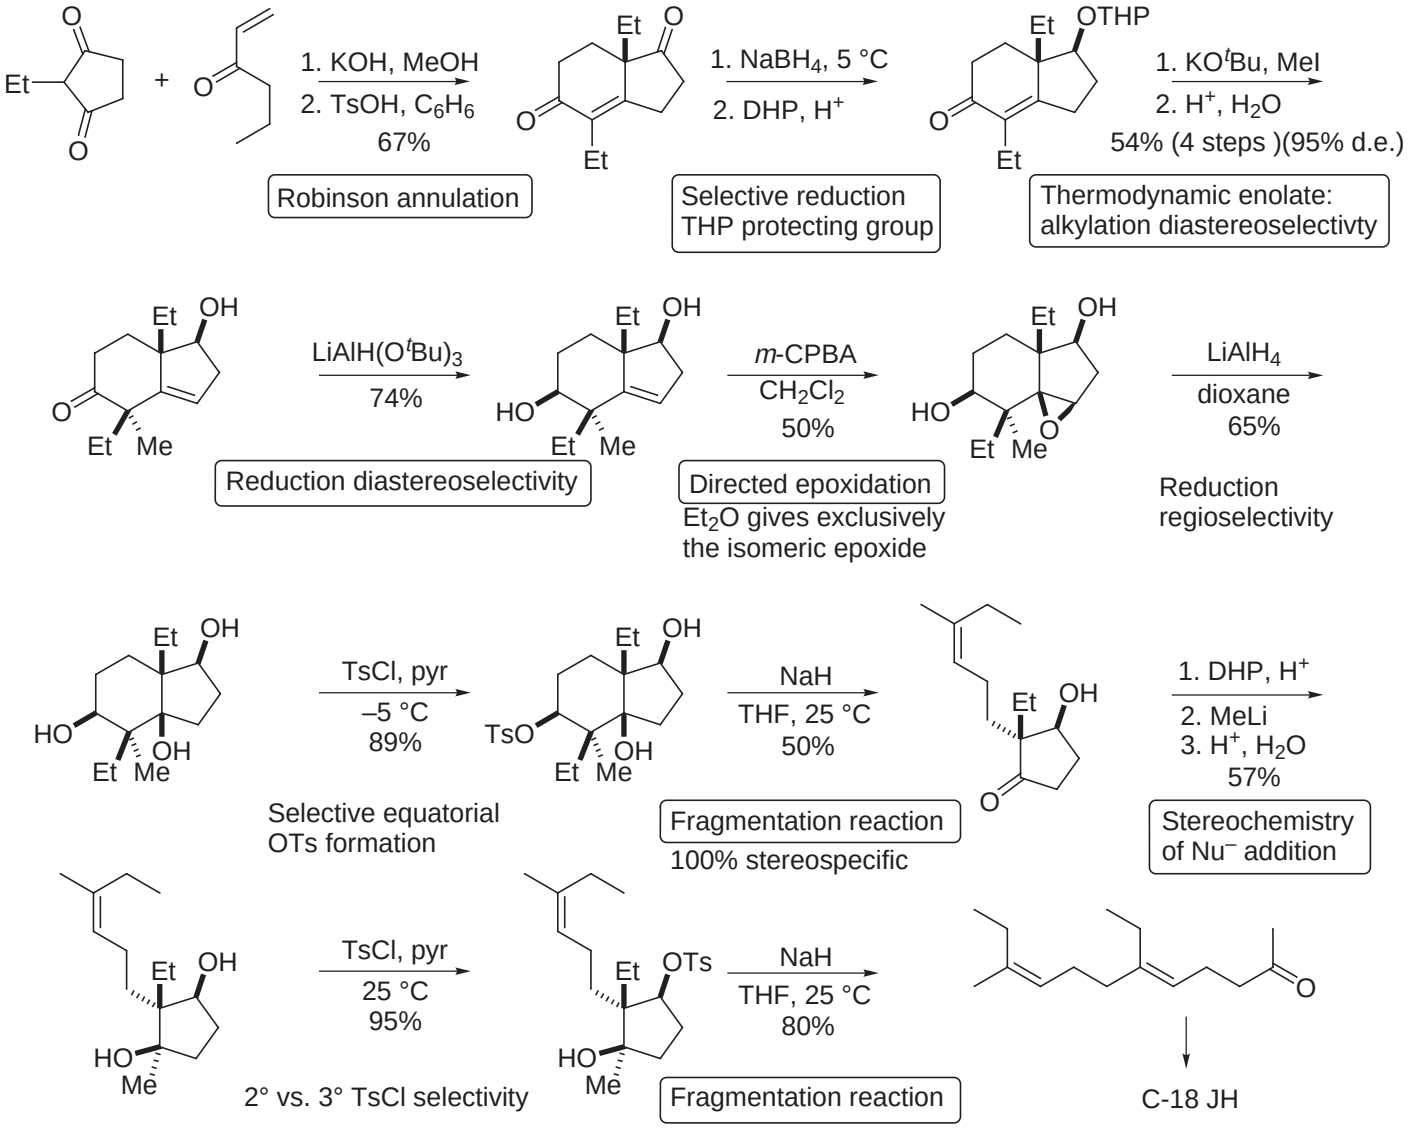
Stereoselectivity
- not much difference between Me and H (second atom steric effect)
- both isomers obtained from the Wadsworth-Horner-Emmons reaction (Modern improvements now available)

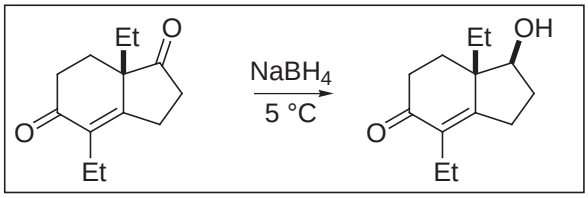


Retrosynthetic Analysis
- repeating subunits recognized
- repeating reactions utilized

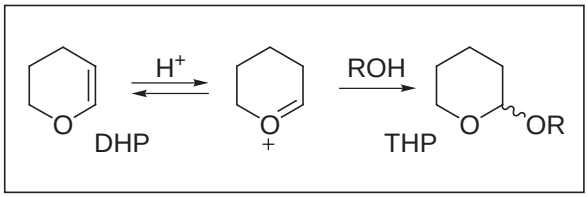
2. Syntex Synthesis: *J. Am. Chem. Soc.* **1968**, *90*, 6224.

Robinson Annulation
Alkylation Diastereoselectivity
Fragmentation Reaction
Directed Epoxidation Reaction

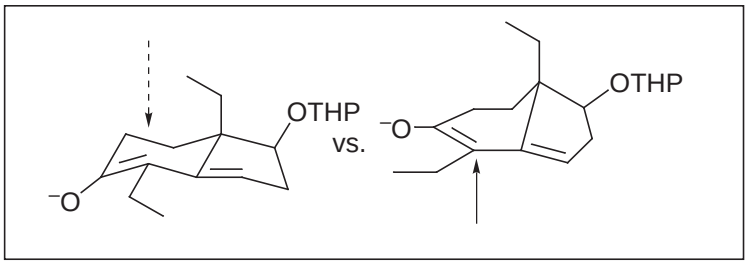




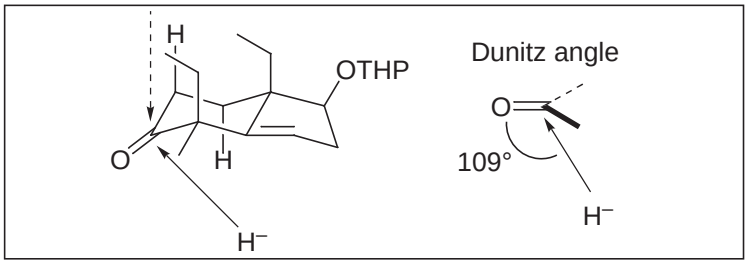
Selective Reduction
- saturated vs. α,β-unsaturated carbonyl
- ring strain associated with 5-membered ring carbonyl released on reduction
- attack from least hindered face



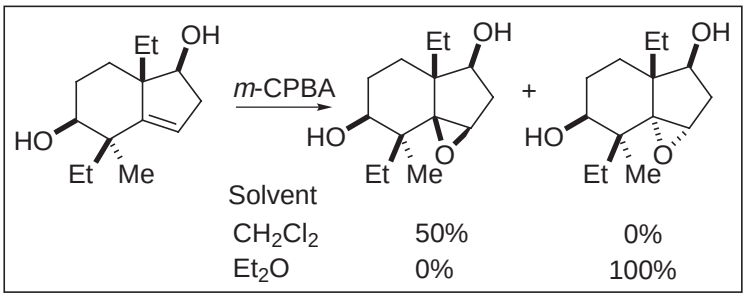
THP Protecting Group
- if R group contains chiral centers, diastereomers result
- removed by mild acid



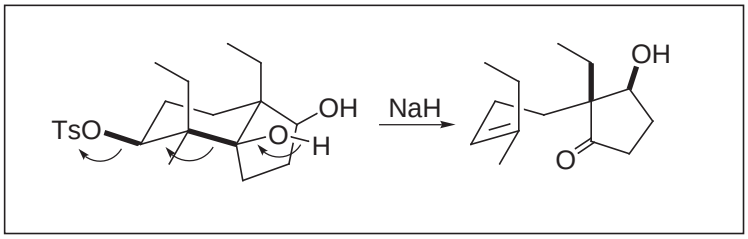
Thermodynamic Enolate
- severe 1,3-diaxial interaction in chair-like T.S. axial alkylation
- no steric incumberance to axial alkylation on least hindered face of twist boat T.S.



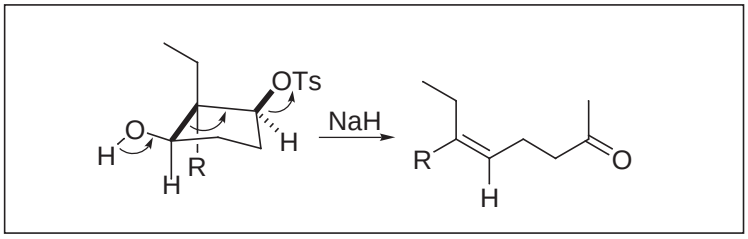
$LiAlH(O^tBu)_3$ Reduction
- large reagent, usually equatorial H^- delivery
- 1,2-interaction (torsional strain) relatively invariant to Nu^- size
- 1,3-steric interaction highly dependent on Nu^- size
- due to absence of axial C(3)-H, large reagent now gives axial delivery



Epoxidation
- in Et_2O, coordination of peracid to solvent gives delivery from the least hindered α-face
- in CH_2Cl_2, coordination of peracid to OH provides delivery to the less accessible β-face
- Teranishi *J. Am. Chem. Soc.* **1979**, *101*, 159.



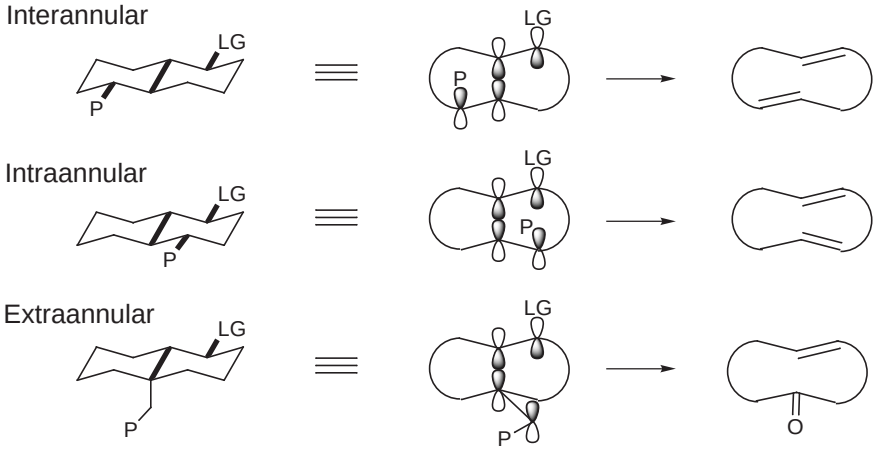
1st Fragmentation
- utilized to control C=C bond stereochemistry
- *trans* periplanar orientation of breaking bonds
- dictates *Z* olefin geometry in product



2nd Fragmentation
- utilized to control C=C bond stereochemistry
- *trans* periplanar orientation of breaking bonds
- dictates *E* olefin geometry in product

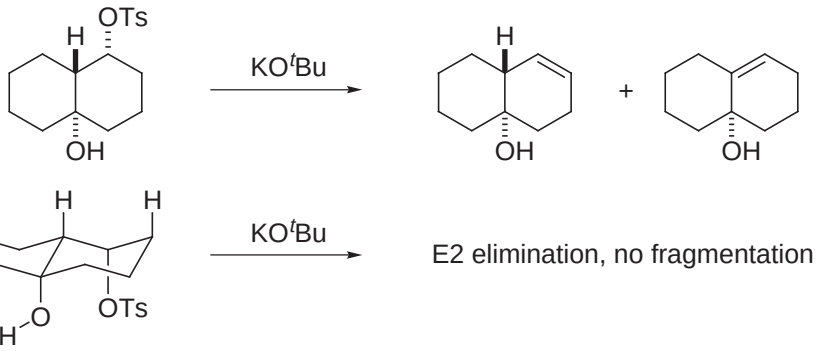
Fragmentation Reactions Grob *Angew. Chem., Int. Ed. Eng.* **1969**, *8*, 535.
Angew. Chem., Int. Ed. Eng. **1967**, *6*, 1.

-Trans periplanar arrangement of participating bond orbital and departing bond orbital

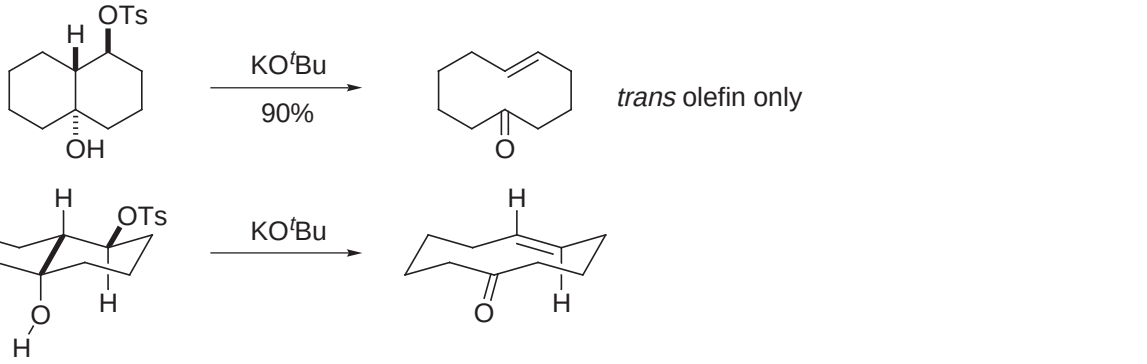


- Wharton *J. Org. Chem.* **1965**, *30*, 3254.
- Fuchs *J. Am. Chem. Soc.* **1979**, *101*, 3567.

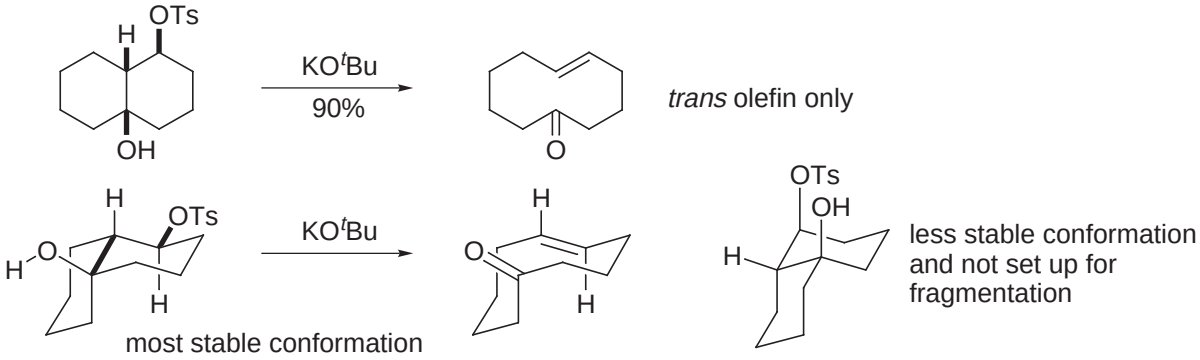
- Case A



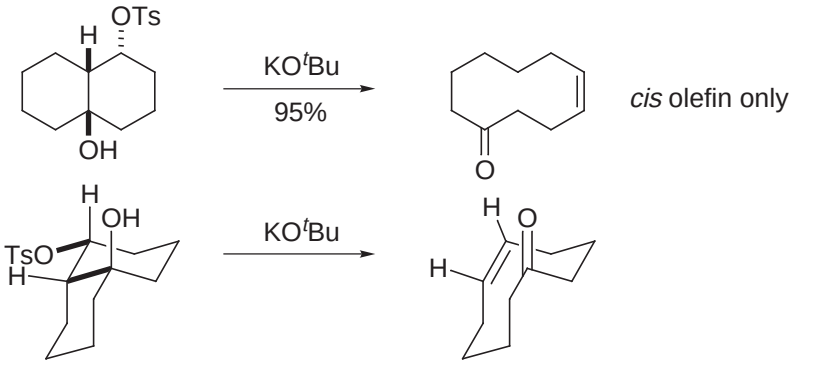
- Case B



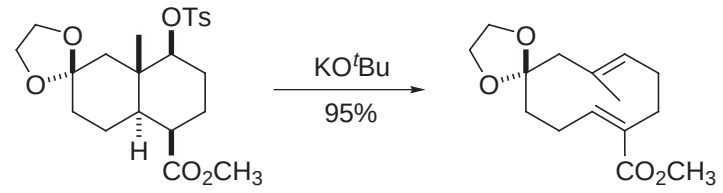
- Case C

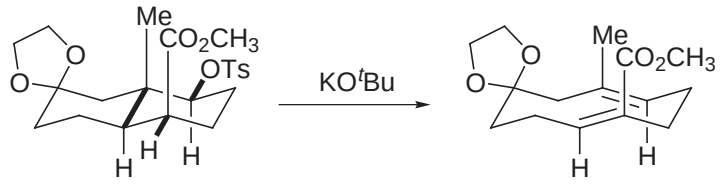


- Case D

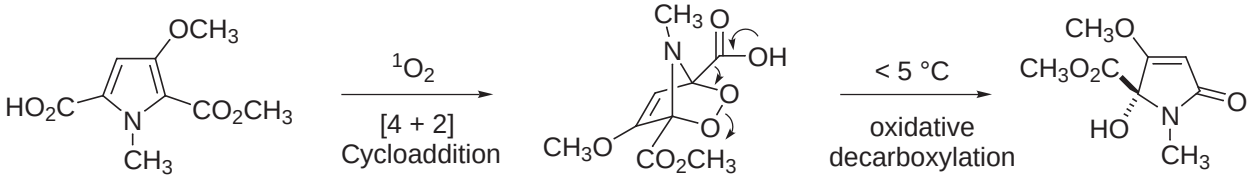


- Other groups at "promoter" site can be used

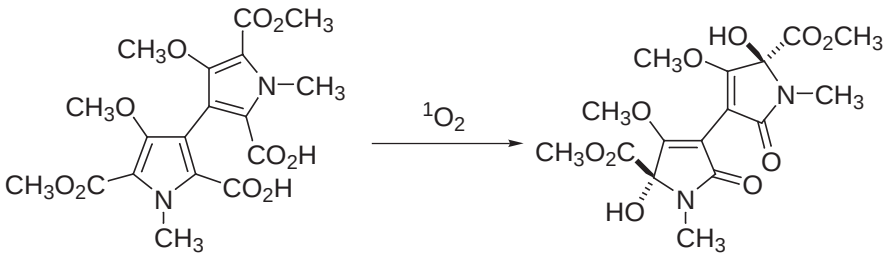




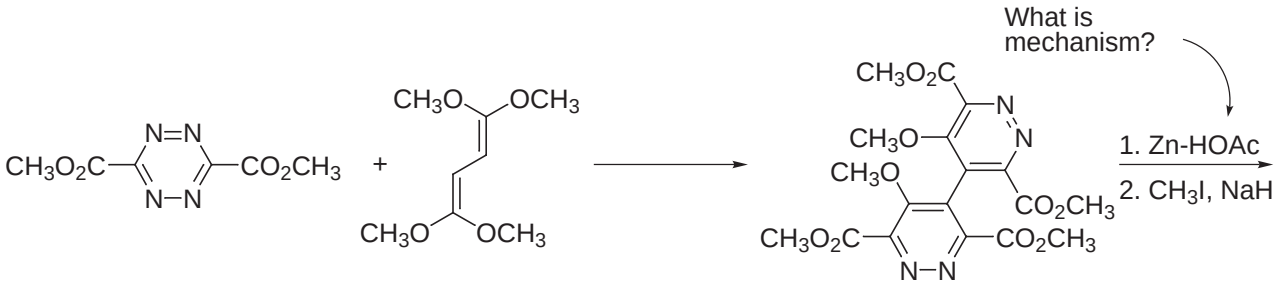
- Many other types of fragmentation reactions

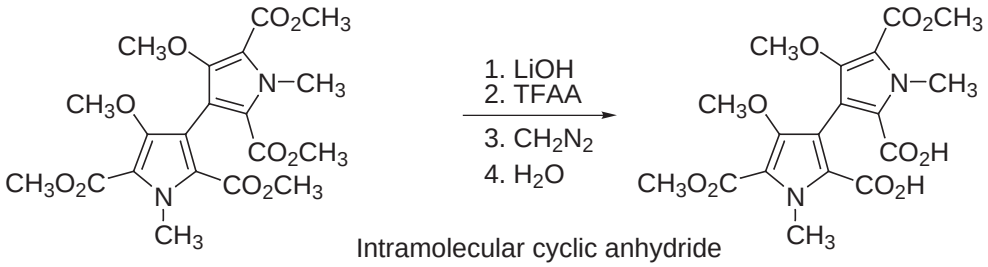


Boger *J. Org. Chem.* **1991**, *96*, 6942.
J. Am. Chem. Soc. **1993**, *115*, 11418.



Isochrysohermidin



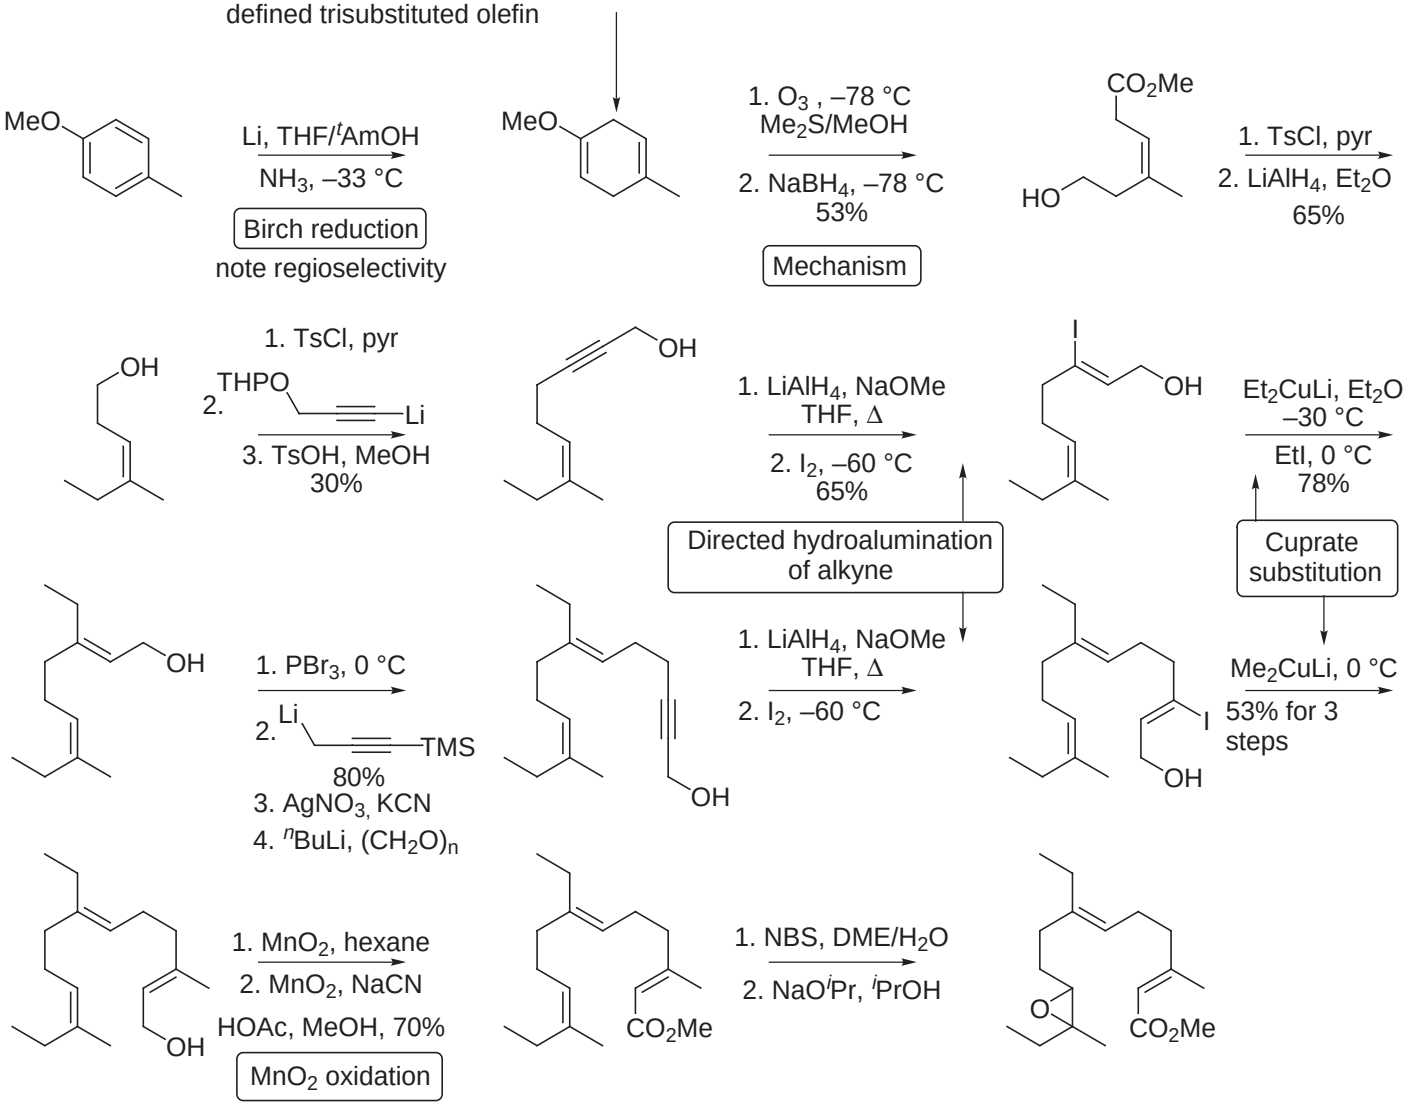


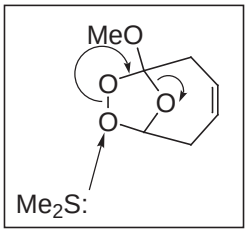
Intramolecular cyclic anhydride formation utilized to differentiate internal acids of tetraacid.

3. Corey Synthesis: *J. Am. Chem. Soc.* **1968**, *90*, 5618.

Dissolving Metal Reductions
Cyclic Precursors to Trisubstituted Olefins
Oxidative Cleavage of Enol Ethers
$LiAlH_4$ Reduction of Propargyl Alcohols
Cuprate Coupling Reactions
Allylic Alcohol Oxidation

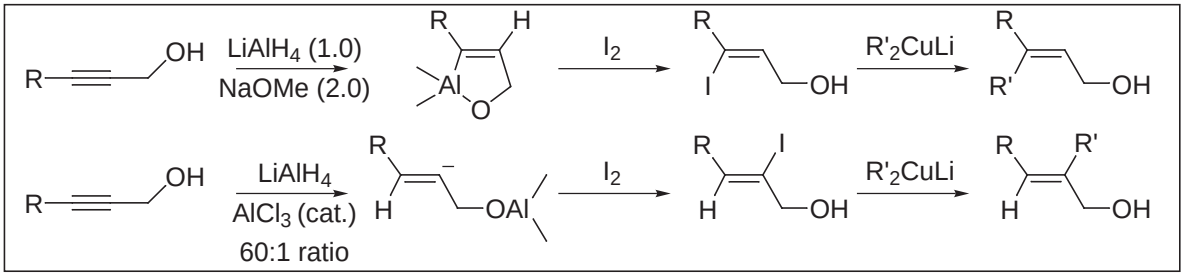
Cyclic precursor to stereochemically defined trisubstituted olefin



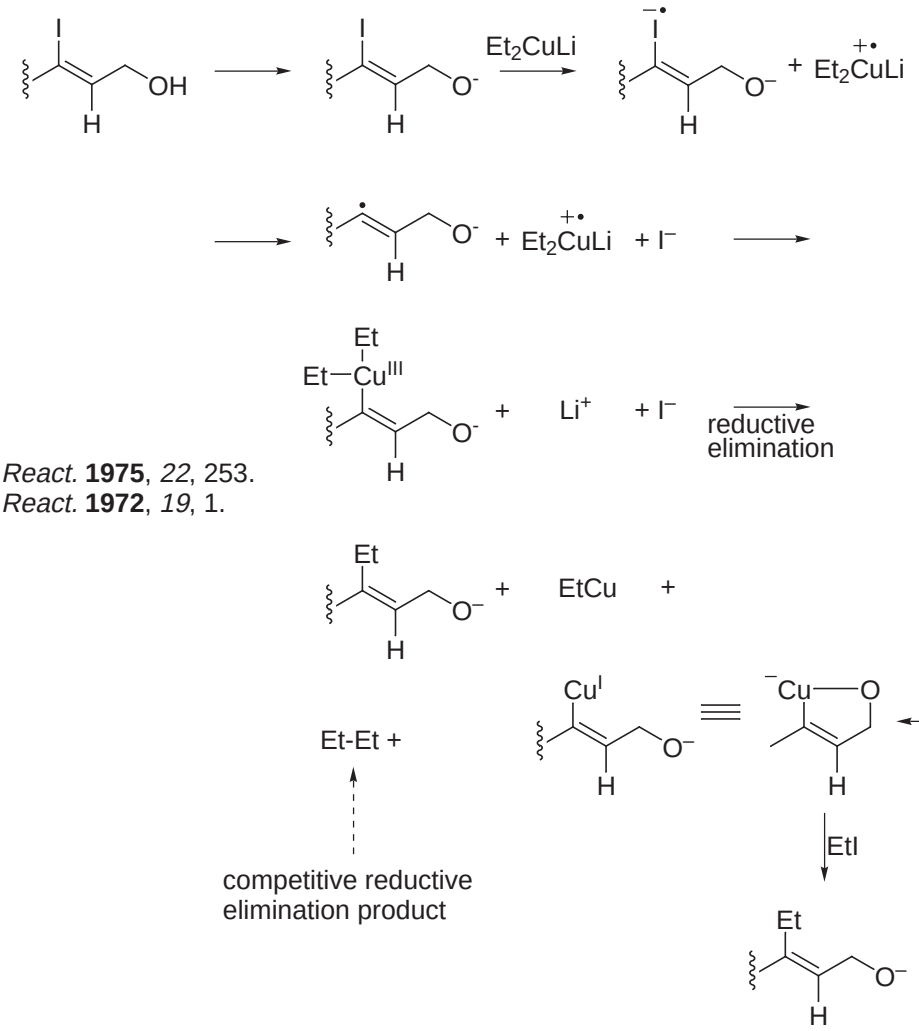


Ozonolysis
- reacts preferentially with more electron-rich C=C
- ring (cleavage) enlisted to control olefin stereochemistry
- addition of MeOH gives methyl ester

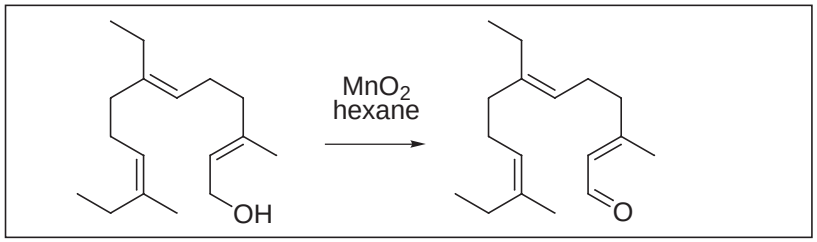
Stereospecific Synthesis of Trisubstituted Olefins
- propargylic alcohols can be reduced with $LiAlH_4$ to give an allylic alcohol



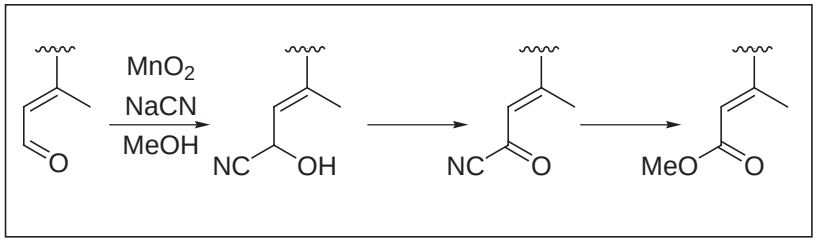
- Cuprate Mechanism

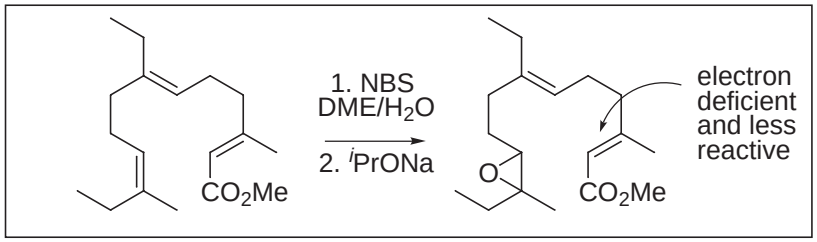


- Posner *Org. React.* **1975**, *22*, 253.
Org. React. **1972**, *19*, 1.



MnO_2 Oxidation
- mild oxidation of allylic alcohols
- direct, mild method for oxidation to a methyl ester

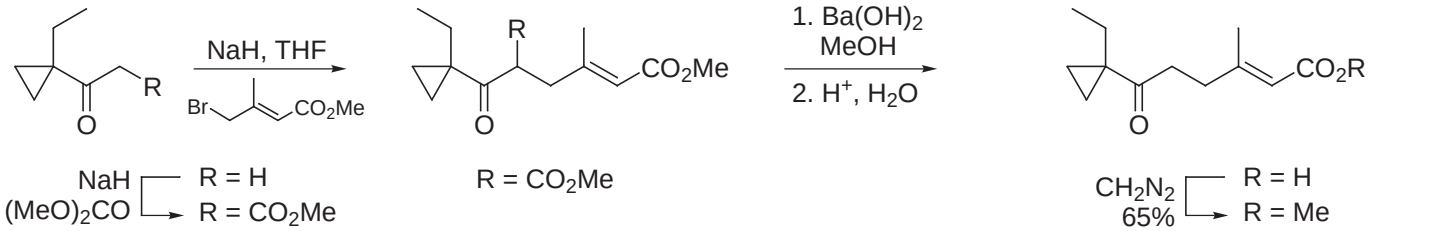


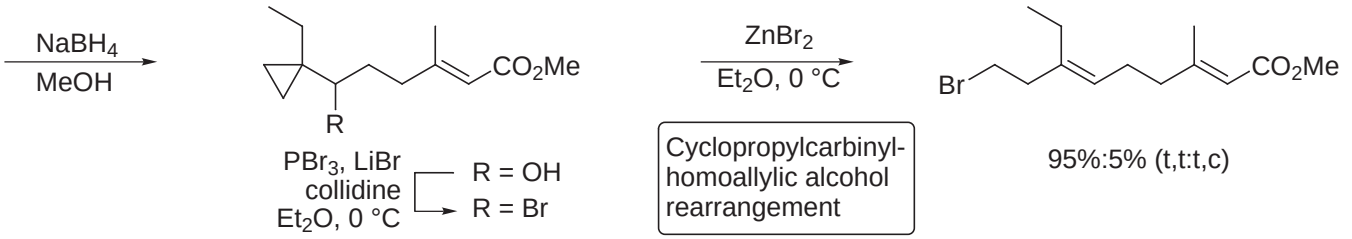


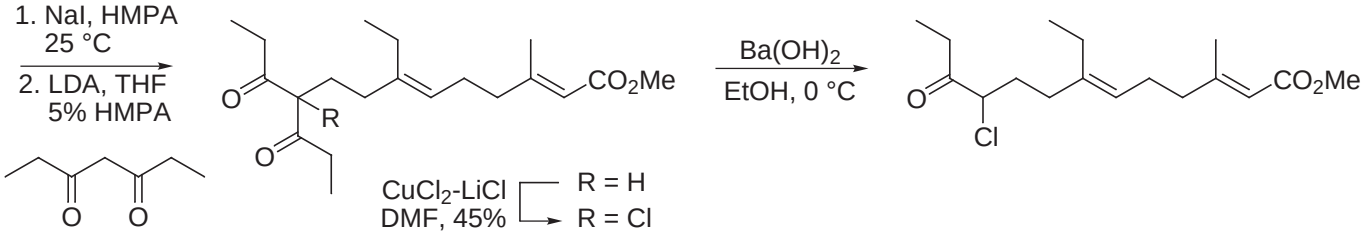
Epoxidation
- selective
- in polar solvent the molecule folds up such that the terminal C=C is more accessible

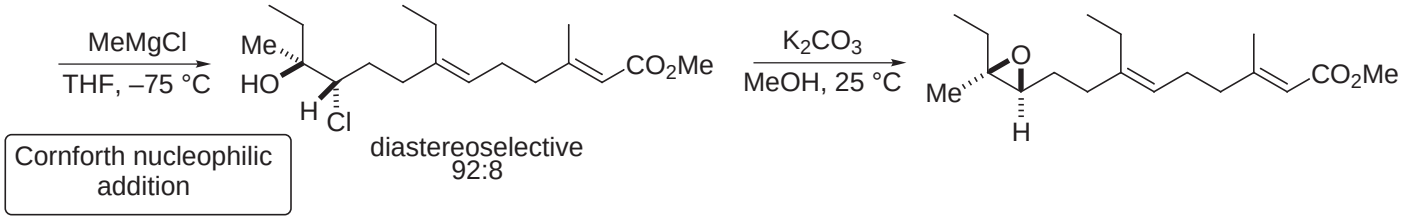
4. Johnson Synthesis: *J. Am. Chem. Soc.* **1968**, *90*, 6225.

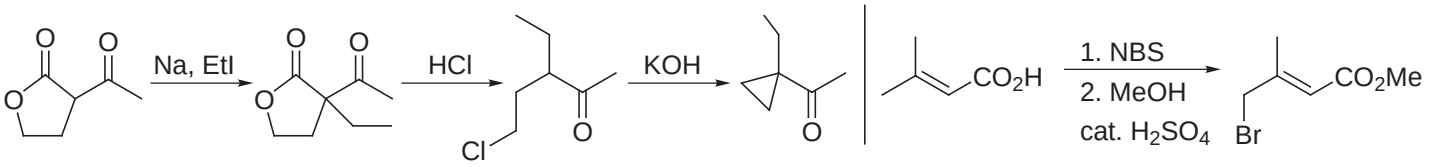
Julia Olefin Synthesis
Cornforth Nucleophilic Addition

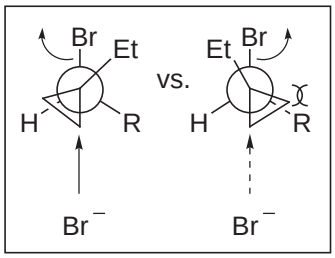




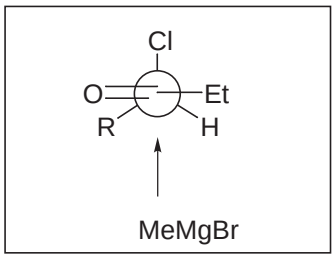








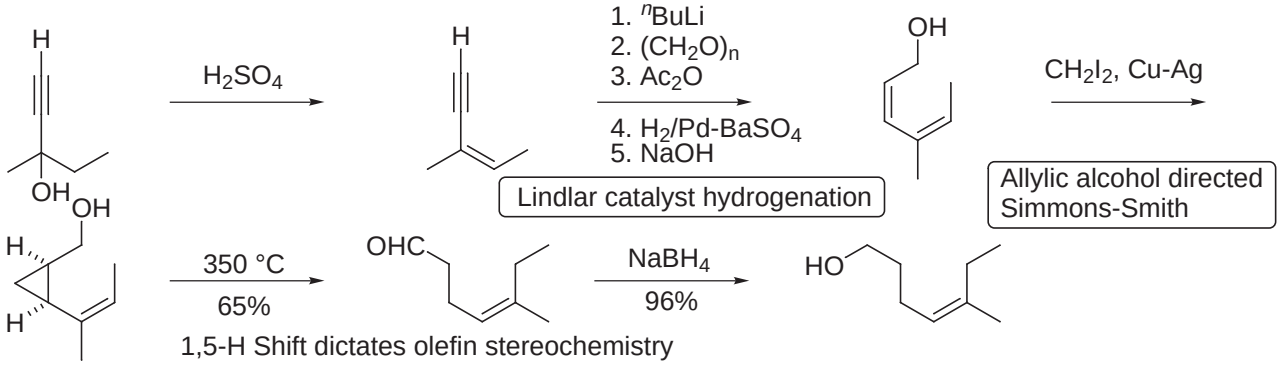
Cyclopropylcarbinyl Bromide Rearrangement
- highly stereoselective modification of Julia olefin synthesis
- Johnson *J. Am. Chem. Soc.* **1968**, *90*, 2882
- Julia *Bull. Soc. Chim., Fr.* **1960**, 1072.
- ring opening concomitant with ionization
- antiperiplanar arrangement of the C-Br and cleaved cyclopropane bond is necessary



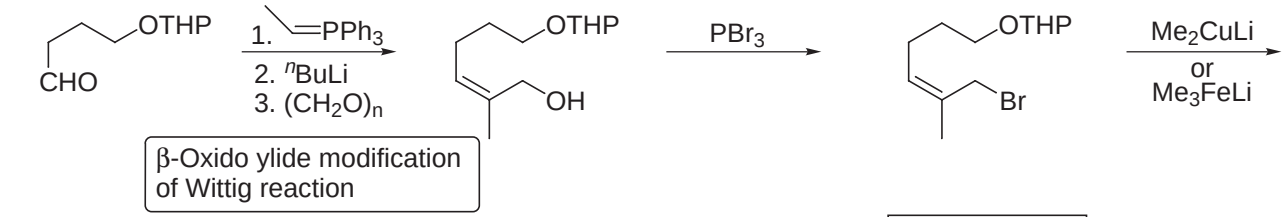
Cornforth Nucleophilic Addition
- *J. Chem. Soc.* **1959**, *112*, 2539.
- earliest generalization of the Felkin model of nucleophilic addition to a carbonyl group in acyclic systems

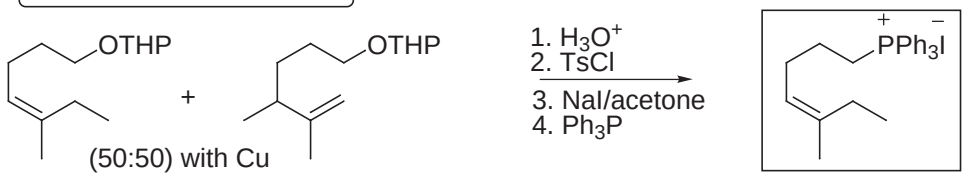
5. Corey Synthesis: *J. Am. Chem. Soc.* **1970**, *92*, 6635, 6636.

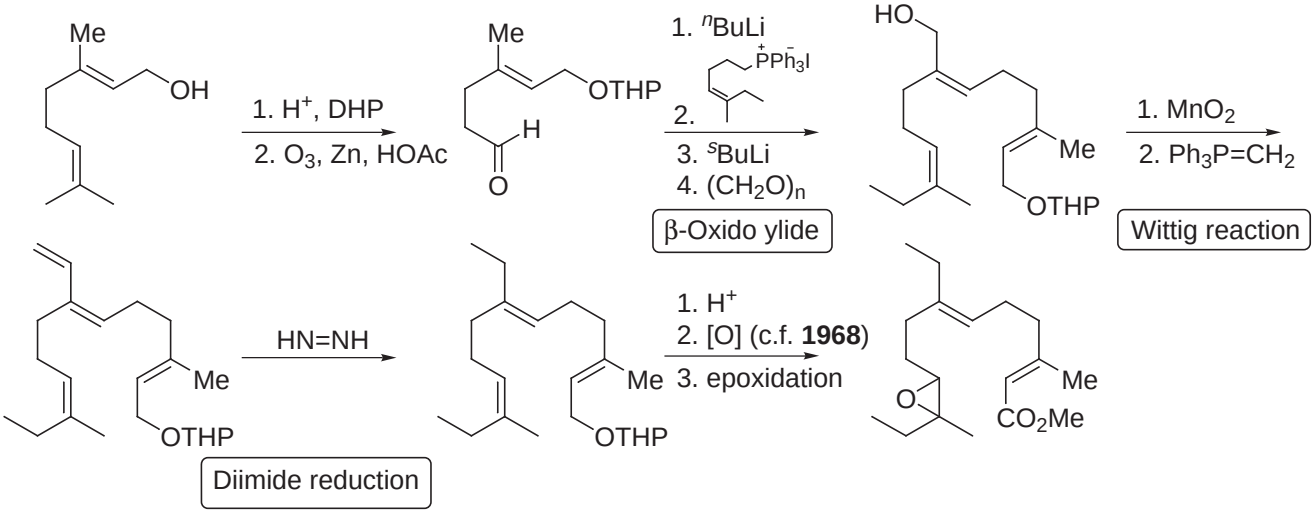
Lindlar Catalyst Alkyne Reduction
1,5-Hydrogen Migration
β-Oxido Ylide Reaction
Diimide Reduction

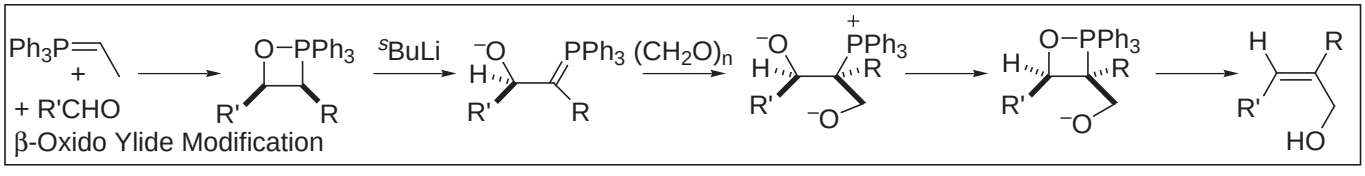


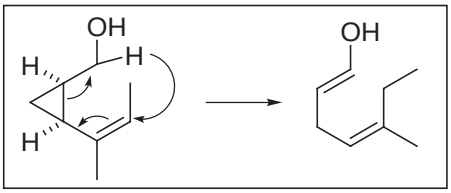
- Alternatively





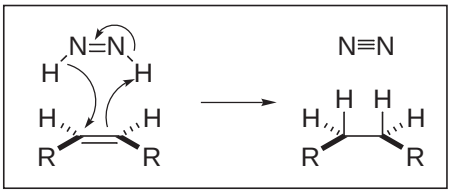






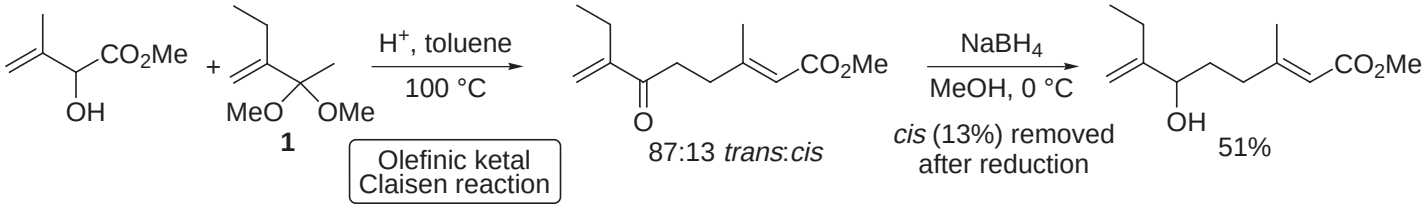
1,5-H Shift

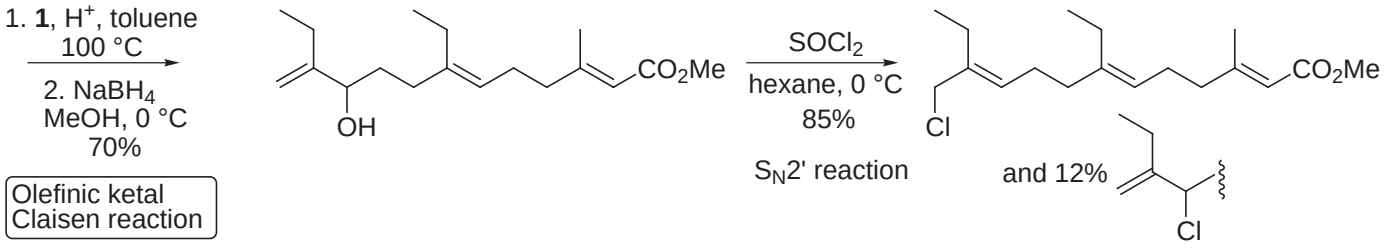
Diimide Reduction
- less substituted C=C reduced more rapidly
- generated *in-situ*
- no dehalogenation

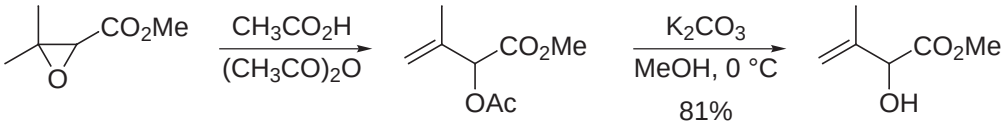


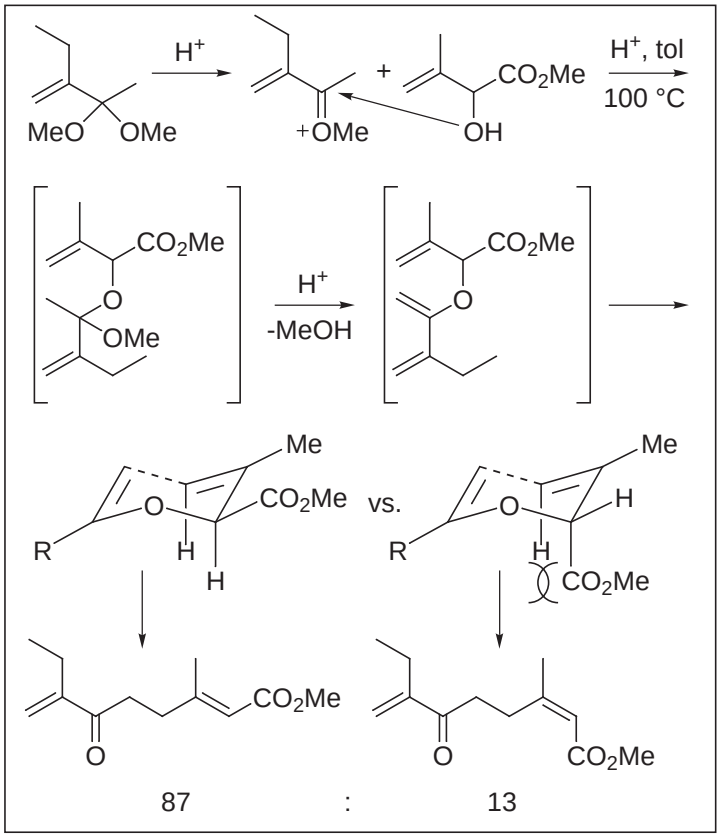
6. Johnson Synthesis: *J. Am. Chem. Soc.* **1970**, *92*, 4463.

3,3-Sigmatropic Rearrangements
Claisen Reaction
Cope Reaction
Oxy-Cope Reaction





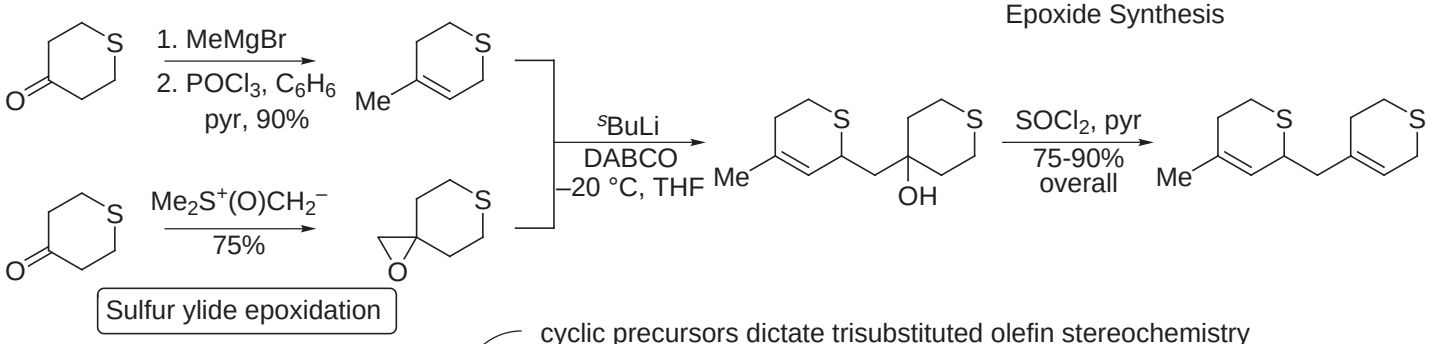


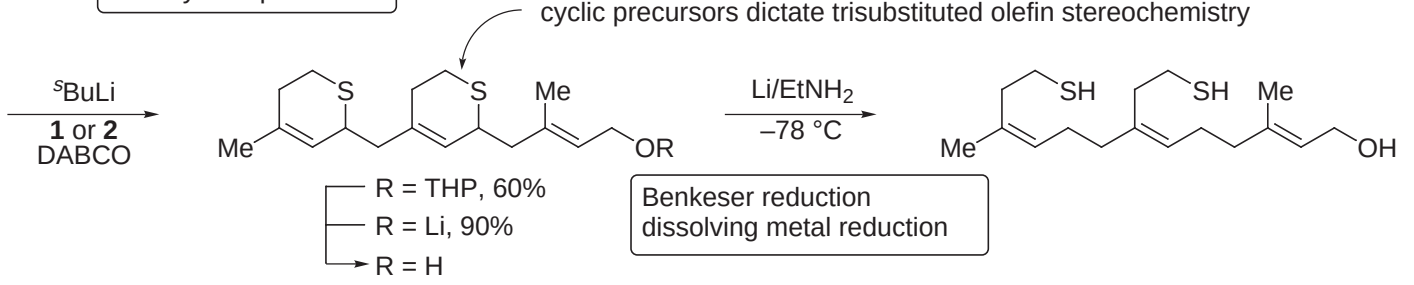


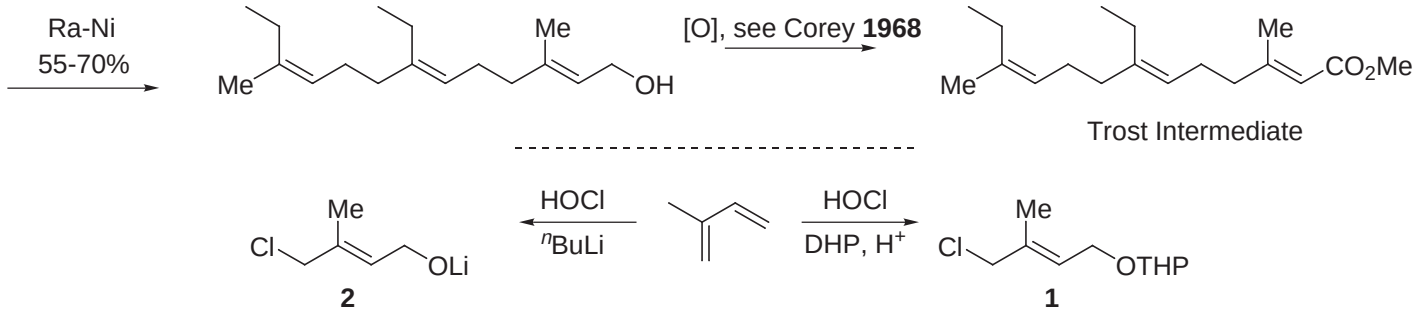
Olefinic Ketal Claisen Reaction
- selectivity dependent on 1,3-interaction in chair-like T.S.
- second Claisen more selective due to larger R group vs. CO_2Me

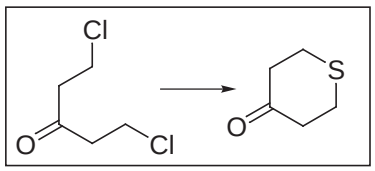
7. Stotter-Kondo Synthesis: *J. Am. Chem. Soc.* **1973**, *95*, 4444.
J. Chem. Soc., Chem. Commun. **1972**, 1311.

Dihydrothiopyran Strategy:
Cyclic Precursors to Trisub. Olefins
Stabilized Allylic Anions
Desulfurization, Benkeser Red.
Sulfur Ylides
Cyclopropane Synthesis
Epoxide Synthesis

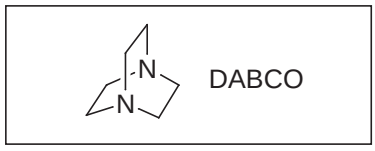




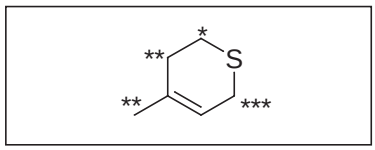




Convergent Route
- symmetrical intermediate

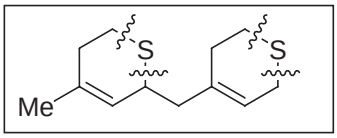


DABCO
- accelerates slow deprotonation
- breaks up Li aggregates

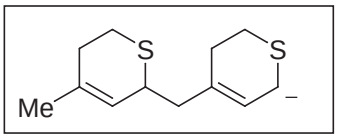


Site of Deprotonation
- at carbon activated by both S and vinyl

Sulfur Ylides: Trost, Melvin *Sulfur Ylides: Emerging Synthetic Intermediates*, Academic Press, 1975.
House, pp. 709.
Benkeser Reduction *Synthesis* **1972**, 391.

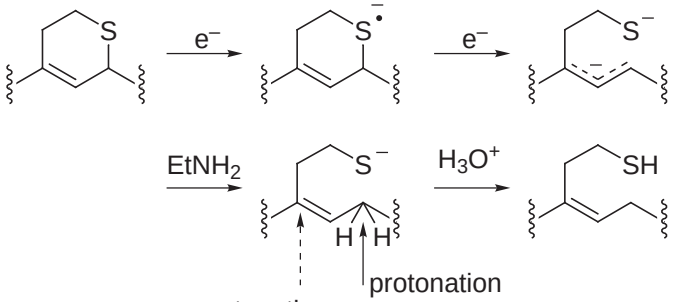


Use of Cyclic Precursors
- control olefin geometry
- insert S, remove with Ra-Ni



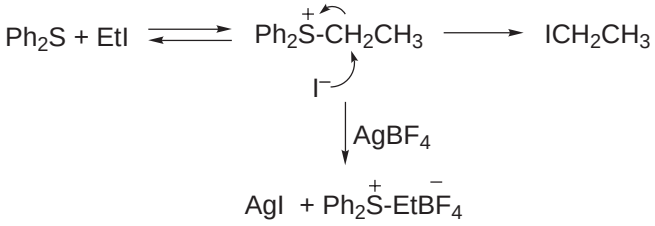
Specific Deprotonation Site
- kinetically preferred site due to sterics
- the thermodynamic and kinetic product
- alkylation occurs cleanly α, not γ, to heteroatom (a well established trend)

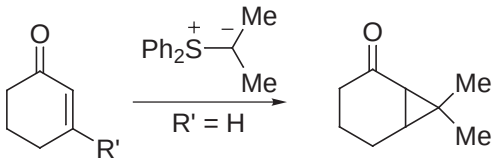
- Li/NH_3 Birch Reduction (blue solution), –33 °C at refluxing NH_3 temperatures
- $Li/EtNH_2$ or $MeNH_2$ Benkeser Reduction (more strongly reducing because of higher reaction temperature)



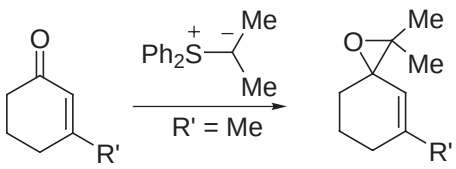
no protonation,
more hindered,
olefin geometry maintained
restricted rotation of allyl
anion π-system

- 1,4-Addition of sulfur ylides -> cyclopropanes



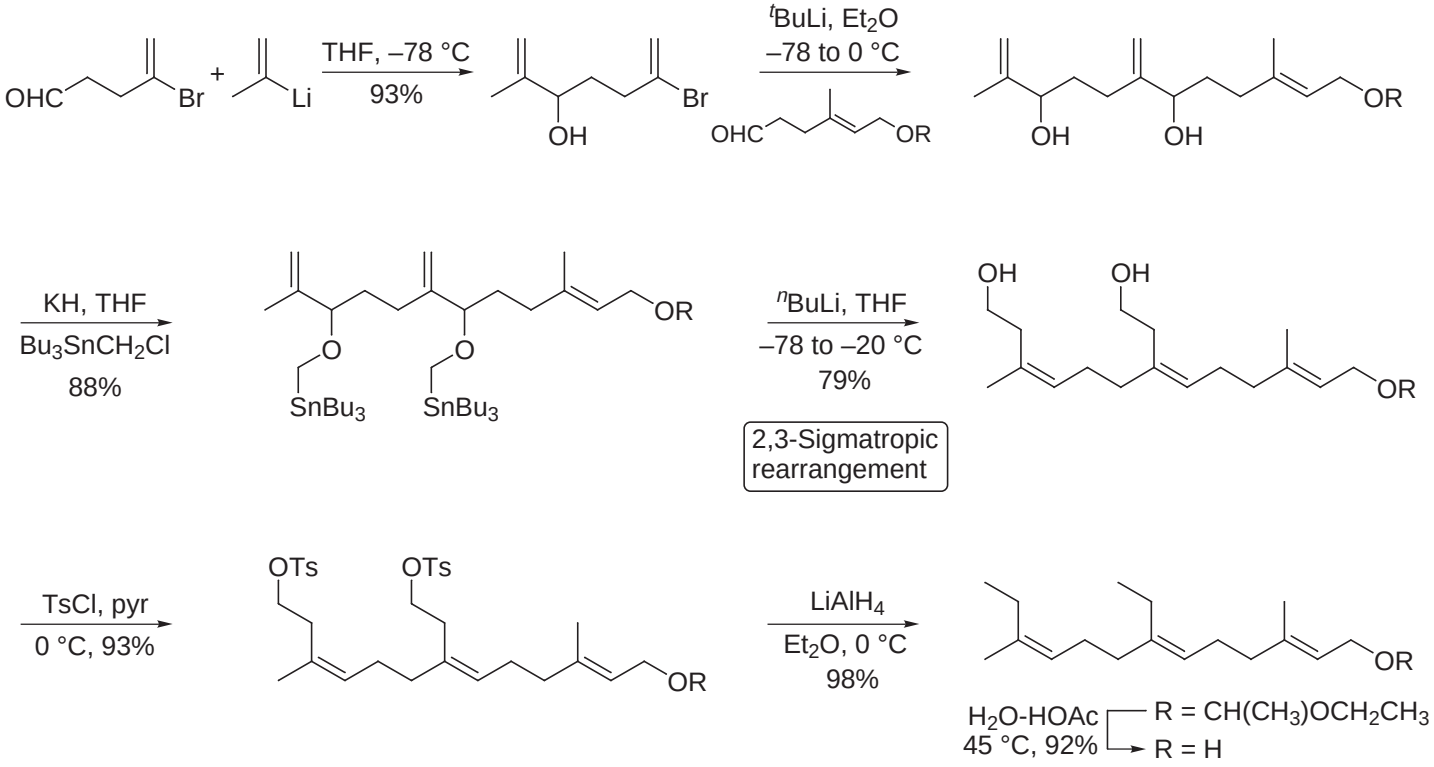


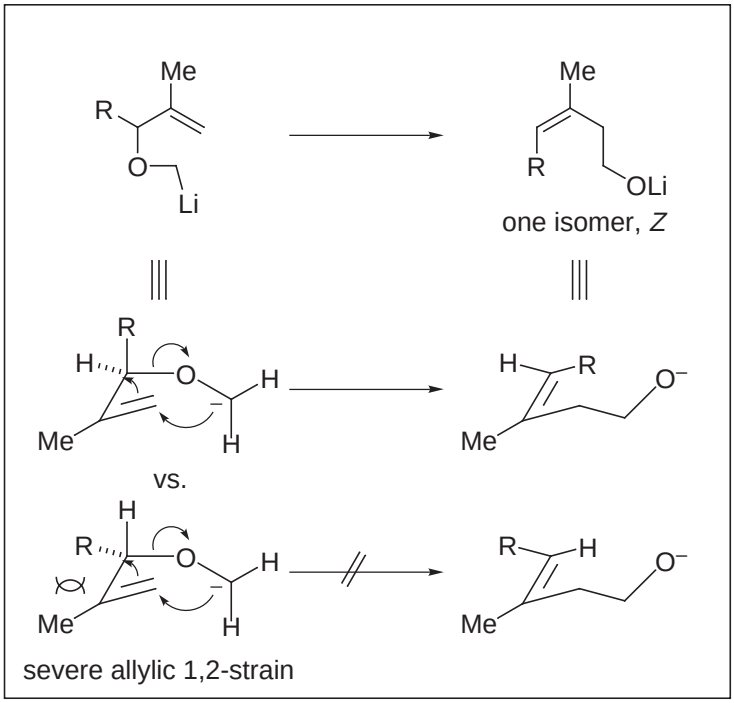
- This reaction is sensitive to substitution pattern on the α,β-unsaturated carbonyl



- In addition, a substituted sulfur ylide increases propensity for epoxide formation over cyclopropane formation

8. Still Synthesis: *Tetrahedron Lett.* **1979**, 593. 2,3-Sigmatropic Rearrangement





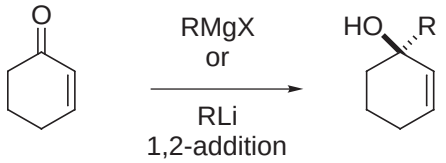
J. Am. Chem. Soc. **1978**, *100*, 1927.

Note: Me substitution on olefin provides *Z* selectivity.

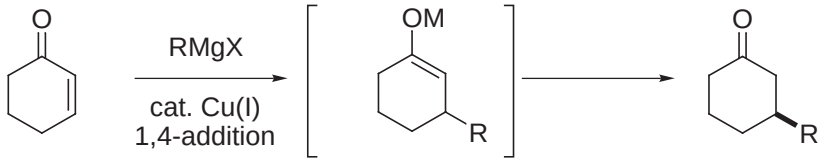
XII. Conjugate Additions: Organocuprate 1,4-Additions

Reviews: House *Acc Chem Res.*, **1976**, *9*, 59.
Ashby *Chem Rev.*, **1975**, *75*, 521.
Comprehensive Org. Syn., Vol. 4, 164.

Review: Lipshutz *Org. React.* **1992**, *41*,135.
Posner *Org. React.* **1975**, *22*, 253.
Posner *Org. React.* **1972**, *19*, 1.

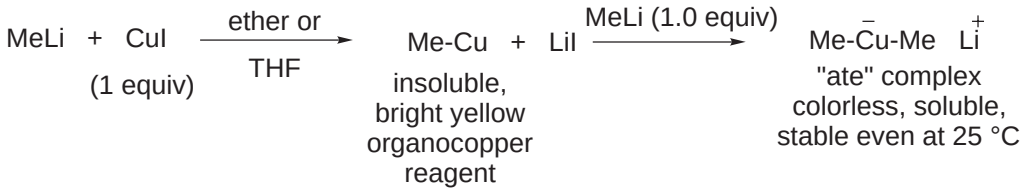


- But Kharasch observed 1,4-addition with added Cu(I) salt:



Kharasch *J. Am. Chem. Soc.* **1941**, *63*, 2308.

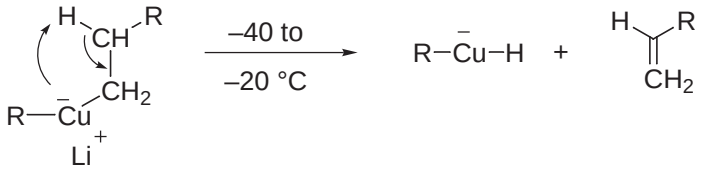
- This led to the development of stoichiometric organocuprate reagents:



House, Whitesides *J. Org. Chem.* **1966**, *31*, 3128.

- "ate" complexes incorporating Li^+ were first described by Gilman (*J. Org. Chem.* **1952**, *17*, 1630) and consequently such reagents are often referred to as "Gilman reagents".

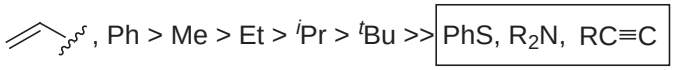
- Most organometallics, including organocuprates, are susceptible to β-elimination:



- So most organocuprates are best handled at temperatures lower than ca. –40 °C.

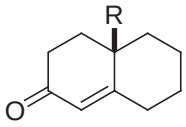
1. Scope

-Relative ease of ligand transfer from Cu follows the order:



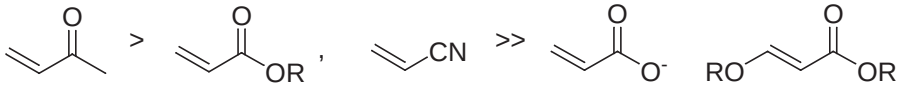
Dummy ligands for mixed cuprates

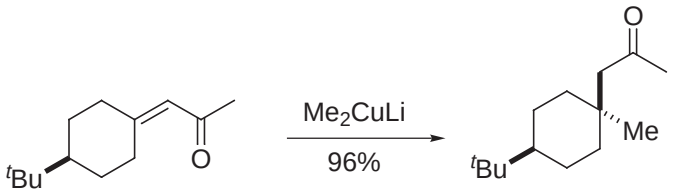
- In addition, the size of the migrating group also affects the conversion:



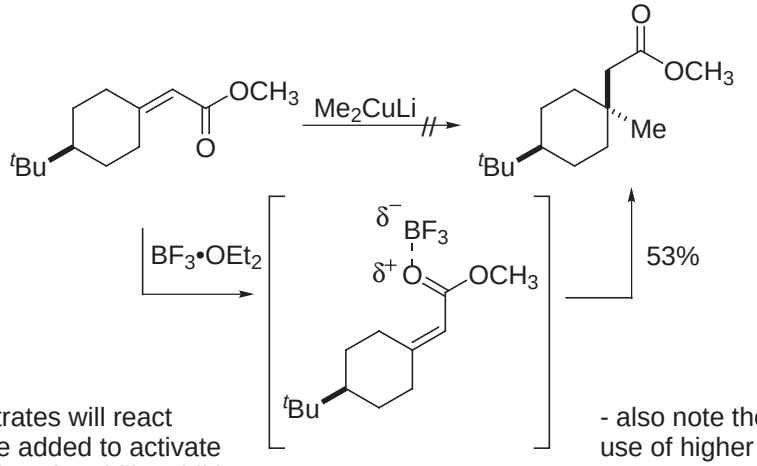
R = H	Me_2CuLi	60–80%	
R = H	Ph_2CuLi	25%	
R = CH_3	Et_2CuLi	55–65%	
R = CH_3	$^{i}Pr_2CuLi$	58%	
R = CH_3	$^{t}Bu_2CuLi$	40%	
R = CH_3	Ph_2CuLi	0%	
R = CH_3		0%	1,2-addition observed

- Effect of substrates:





- Unsaturated esters are less reactive than enones.
- β,β-Disubstitution slows reaction.

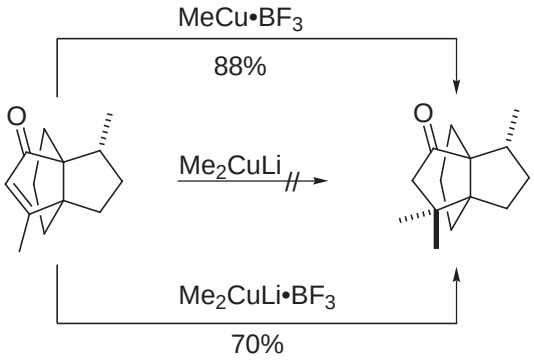


- unreactive substrates will react if Lewis acids are added to activate substrate toward nucleophilic addition.

- also note the alternative use of higher order cuprates $[R_2CuCN]Li_2$.

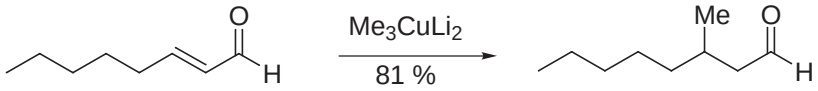
Maruyama *J. Am. Chem. Soc.* **1977**, *99*, 8068.
Yamamoto *J. Am. Chem. Soc.* **1978**, *100*, 3240.

$RCu•BF_3$
Yamamoto *J. Am. Chem. Soc.* **1980**, *102*, 2318.
Yamamoto *J. Org. Chem.* **1979**, *44*, 1745.



Review: Yamamoto *Angew. Chem., Int. Ed. Eng.* **1986**, *25*, 947.

- Conjugate addition to α,β-unsaturated aldehydes is typically problematic but successful examples have been reported.



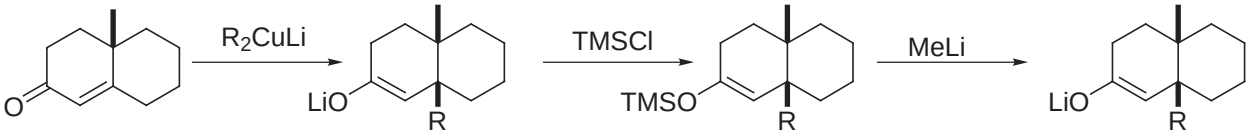
Still *Tetrahedron Lett.* **1976**, 2659.
Meyer *Org. Prep. Proceed.* **1979**, *11*, 97.
Clive *J. Chem. Soc., Chem. Commun.* **1981**, 643. ($Me_5Cu_3Li_2$)
Clive *J. Org. Chem.* **1982**, *47*, 2572.

Conjugate Addition/Alkylation (stereochemistry)
Posner *J. Org. Chem.* **1979**, *44*, 3661.
Review: *Comprehensive Org. Syn.,* Vol. 4, pp. 237-268.

Conjugate Addition/Aldol
Heng *Tetrahedron* **1979**, *35*, 425.

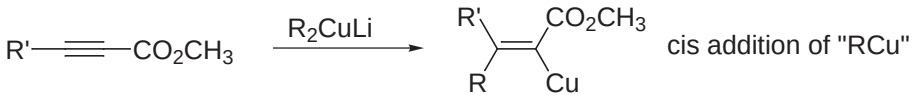
- Cuprates can also be prepared from other organometallic reagents which have greater compatibility with reactive groups:
e.g. activated $Cu^{(0)}$/RBr, RZnI, $RSnBu_3/Me_2Cu(CN)Li_2$, $RCH=CH_2$/ $Cp_2Zr(H)Cl$ then $CuBr•SMe_2$

- Useful in the regiospecific trap and subsequent generation of enolates.



Stork *J. Am. Chem. Soc.* **1974**, *96*, 7114.
Stork *J. Am. Chem. Soc.* **1961**, *83*, 2965.
Horiguchi *Tetrahedron Lett.* **1989**, *30*, 7087.

- Additions to acetylenes



cis addition of "RCu"

R' = Et R = CH_3

THF at –100 °C	97:3	*cis*:*trans*
THF at –78 °C	92:8	lower stereoselectivity due to configurational instability of alkenyl copper reagent
toluene (3 h)	92.5:7.5	
ether (3 h)	24:76

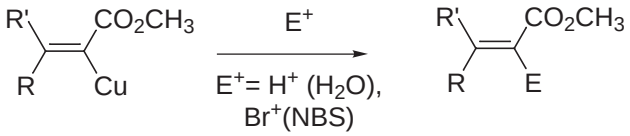
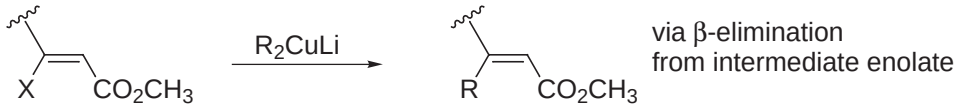
Klein *J. Chem. Soc., Perkin Trans. 2* **1973**, 1971.

- Alkenyl copper intermediates can be subsequently trapped:

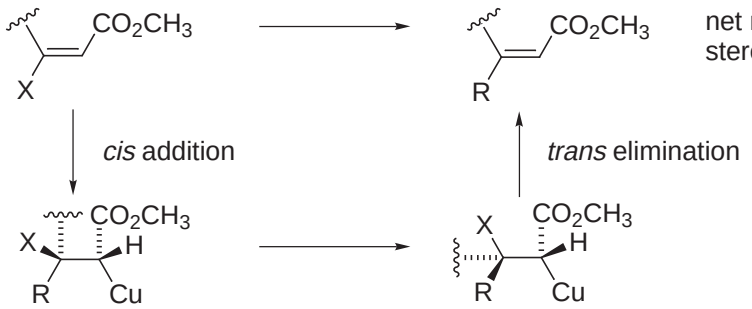


- Also, used in displacement of leaving groups (addition/elimination reactions).



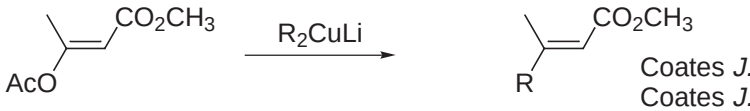
via β-elimination
from intermediate enolate

X = SPh, Br, OAc (good leaving group)

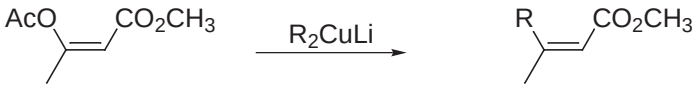


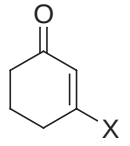
X = SPh
Corey *J. Am. Chem. Soc.* **1969**, *91*, 1851.
Casey *Tetrahedron Lett.* **1974**, 925.
Mukaiyama *Chem Lett.* **1974**, 705.

- Examples:

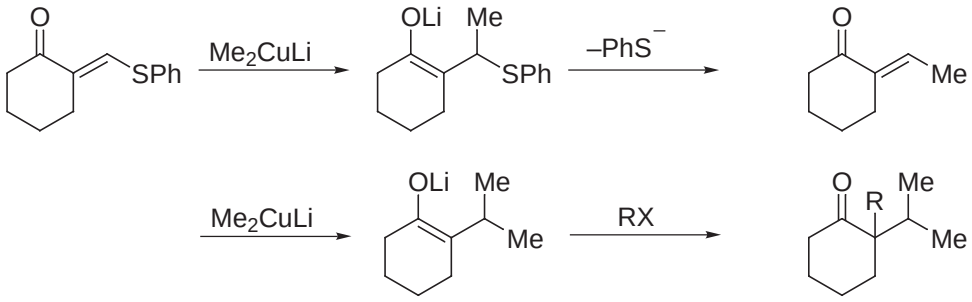


Coates *J. Org. Chem.* **1974**, *39*, 275.
Coates *J. Am. Chem. Soc.* **1971**, *93*, 1027.
Corey *Tetrahedron Lett.* **1973**, 3817.

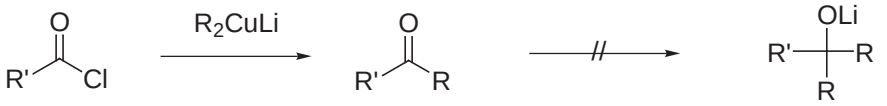




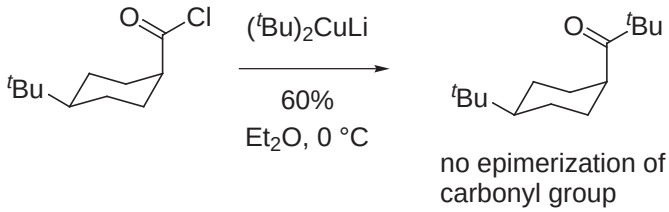
X = SPh, Cl, Br, OAc
(but not for OCH_3)



- Selective preparation of ketones from carboxylic acid derivatives.

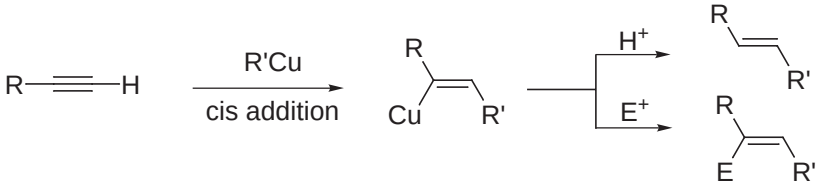


no overaddition
to give 3° alcohol

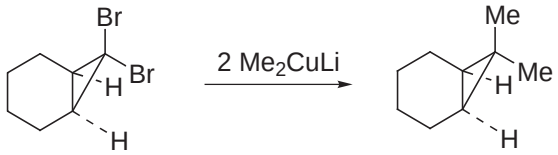


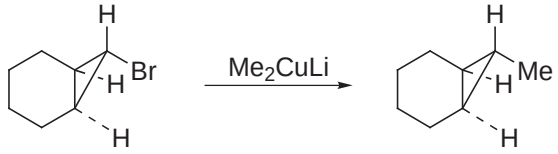
no epimerization of axial
carbonyl group

- Additions to terminal alkynes.

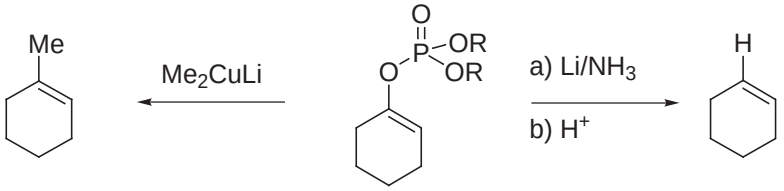


- Alkylation reactions

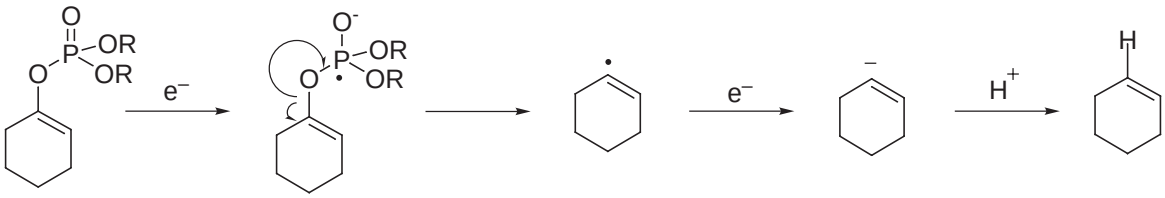




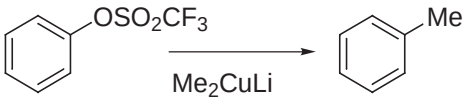
substitution reactions proceed with retention of configuration



- Mechanism:

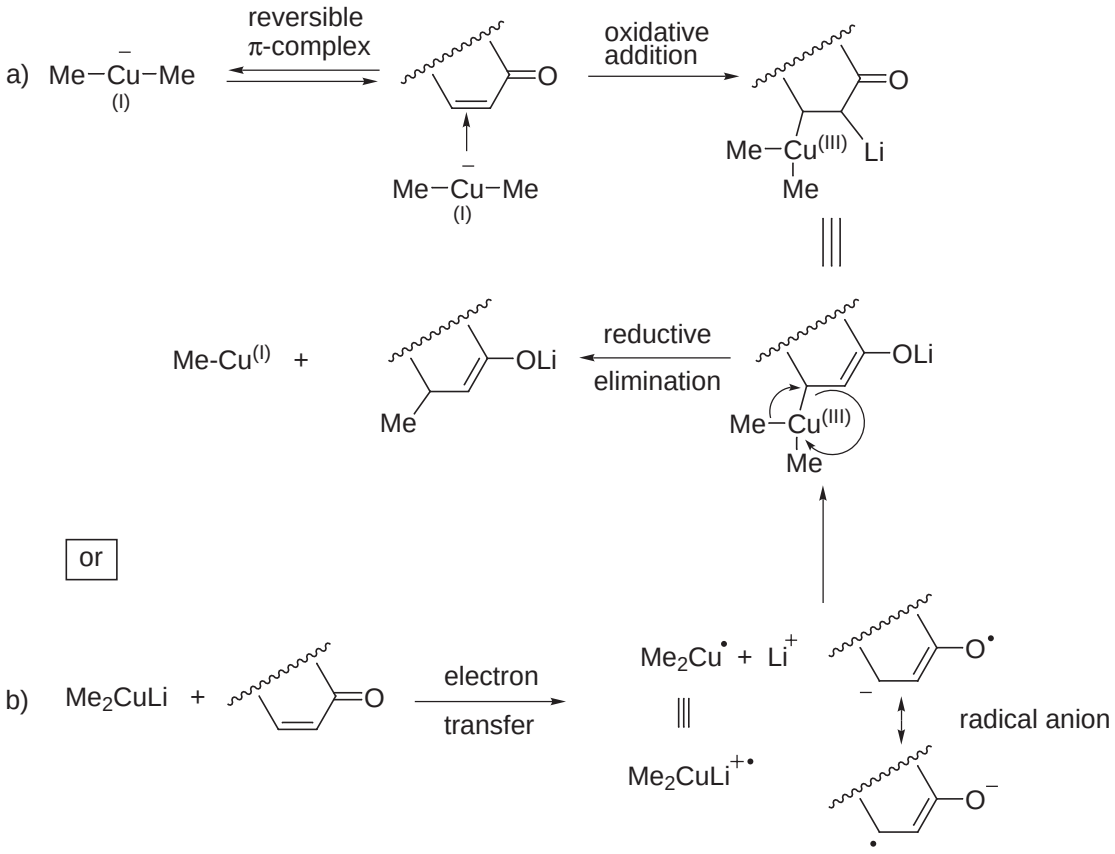


- Also can be conducted with aryl and enol triflates



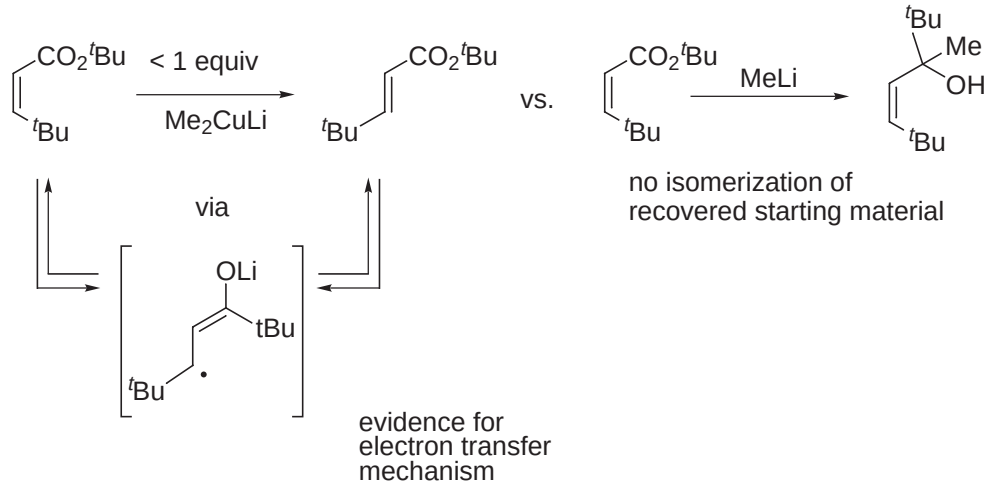
functional group reactivity~ RCOCl > CHO > tosylates > epoxides > bromides > ketones > esters > nitriles

2. Mechanism



-Evidence for mechanism b)

i. Isomerization and recovery of substrates without 1,4-addition



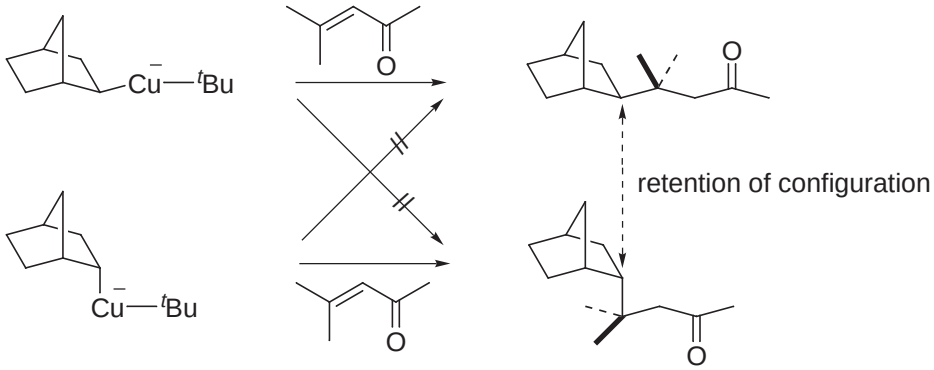
ii. Cation is essential for the reaction $Me_2Cu(Li)$

- if crown ethers are added to reaction mixture, reaction is slowed or prevented

- Li^+ complexes with carbonyl oxygen and activates substrate to conjugate addition (Ouannes *Tetrahedron Lett.* **1977**, 815.)

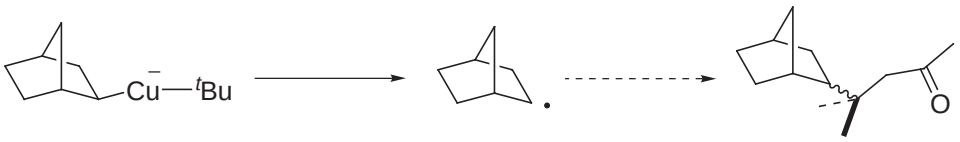
iii. Retention of stereochemistry of cuprate alkyl group that is transferred

e.g.



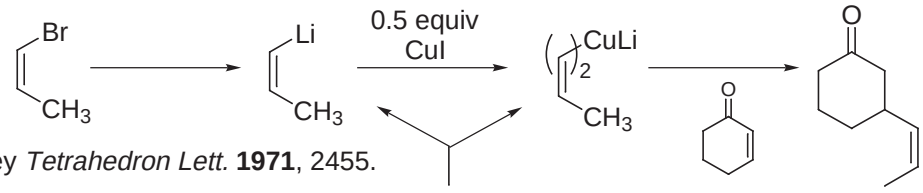
Whitesides *J. Org. Chem.* **1972**, *37*, 3718.
Whitesides *J. Am. Chem. Soc.* **1969**, *91*, 6542.

- So reaction cannot be proceeding through a free-radical



would get mixture

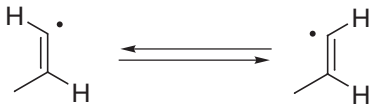
- Retention also observed for alkenyl cuprates:



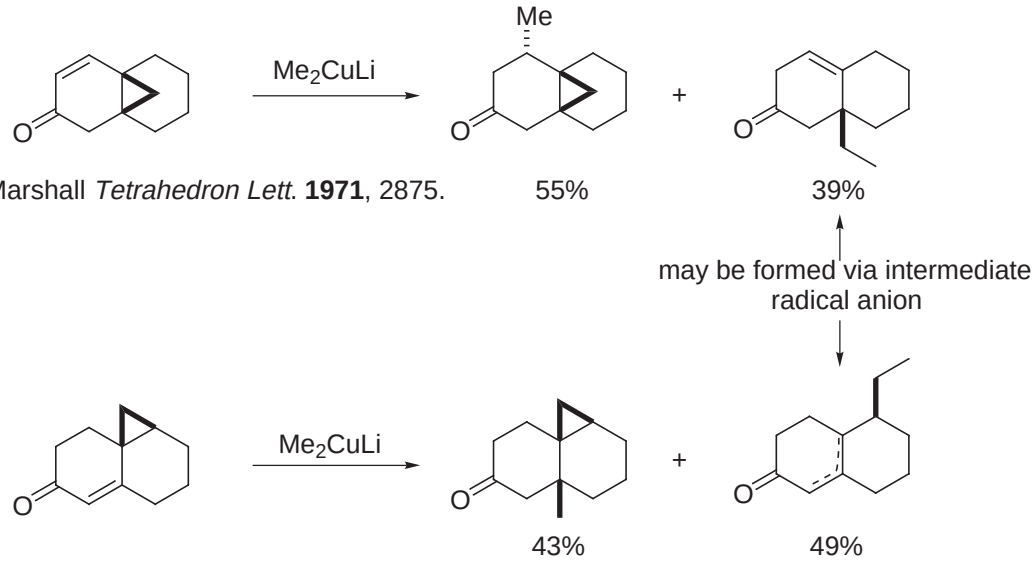
Casey *Tetrahedron Lett.* **1971**, 2455.

Configurationally stable

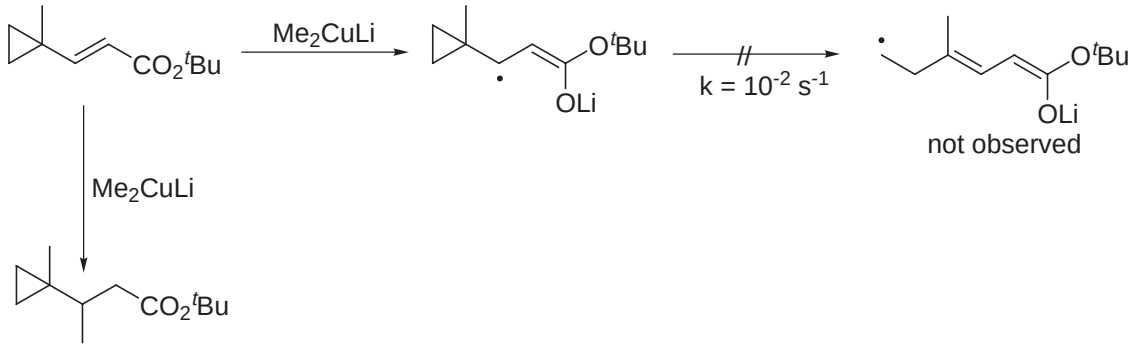
- Not true for free radical

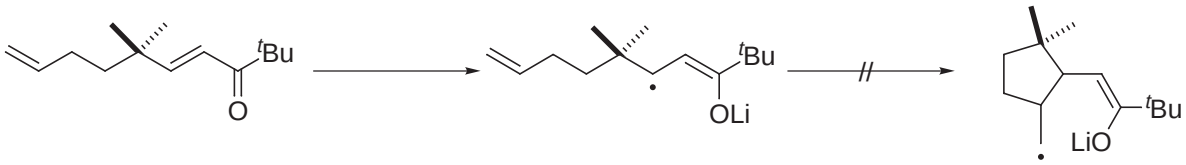


- Additional evidence for radical anion mechanism:



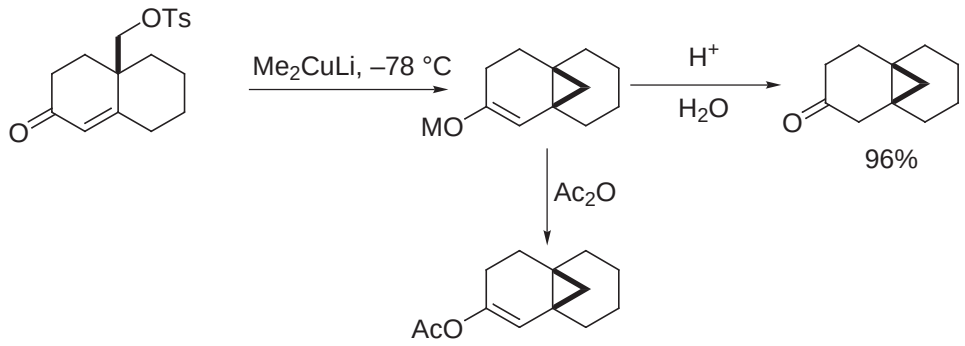
- but





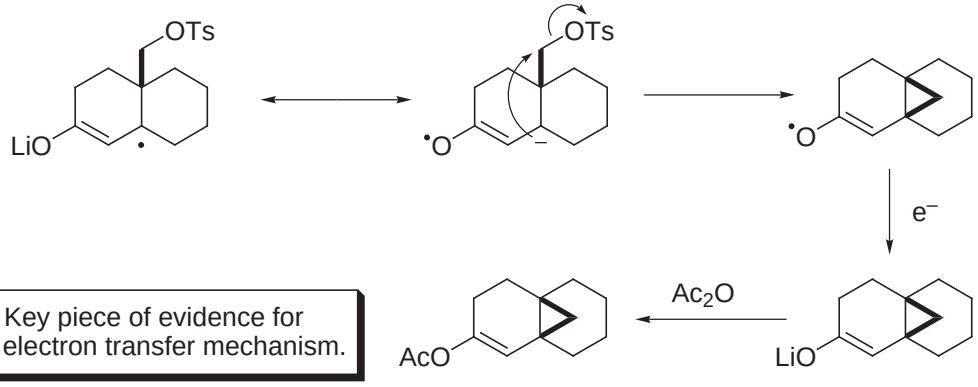
- So half-life of intermediate radical anion is very short.
- Subsequent coupling with cuprate reagent (after e^- transfer) is faster than other radical reactions in some cases.
- However, competitive single electron reductions with cuprates have been observed and they may be used to effect reductive elimination reactions in manner analogous to dissolving metal or Zn reductions.

iv. Trap of intermediate radical anion



- no conjugate or homo-conjugate addition observed, only intramolecular trap of intermediate radical anion

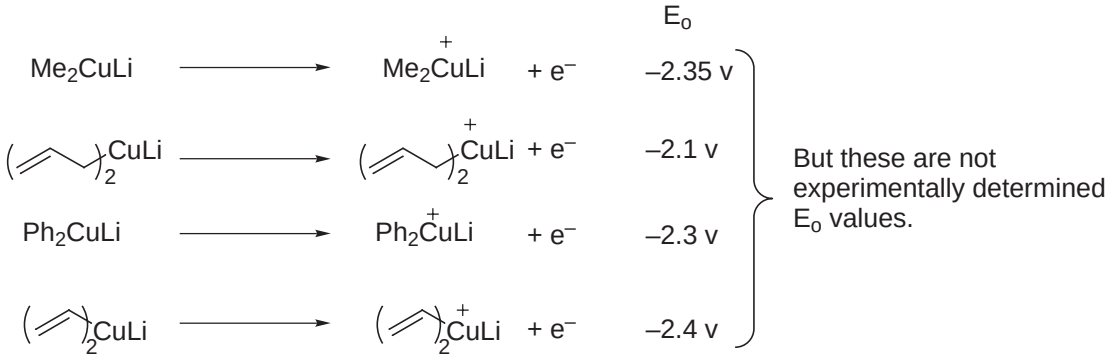
Hannah *Tetrahedron Lett.* **1975**, 187.



- Key piece of evidence for electron transfer mechanism.

v. House *J. Am. Chem. Soc.* **1972**, *94*, 5495.

- Rate and ease of conjugate addition to the substrate correlate with the polarographic reduction potential while they do not always correlate with propensities for Michael addition.



- And for conjugate addition with Me_2CuLi

	E_{red}		E_{red}
	–1.63 v		–2.26 v
	–2.13 v		–2.25 v
	–2.14 v		–2.33 v
	–2.12 v		–2.35 v
	–2.20 v		

All can accept an e^- (undergo reduction) by Me_2CuLi.

E_o = –2.35 v

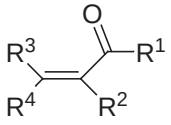
- But these substrates do not react with Me_2CuLi:

	–2.43 v		–2.50 v
	–2.54 v		–2.55 v

Note that for  the ease of organocuprate conjugate addition decreases in the order:

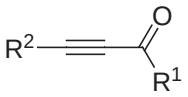
E = COR > CO_2R > CN House *Acc. Chem. Res.* **1976**, *9*, 59.

-House estimation of



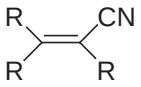
base value = –1.9 v

substituent	R^1	R^2	R^3/R^4
alkyl	–0.1	–0.1	–0.1
alkoxy	–0.3	0	–0.3
phenyl	+0.4	+0.1	+0.4



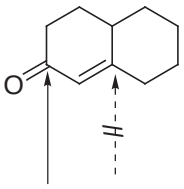
base value = -1.8 v

substituent	R^1	R^2
alkyl	–0.1	–0.1
alkoxy	–0.3	---

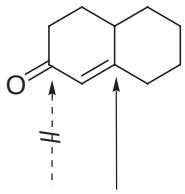


base value = –2.3 v

vi. Kinetic preference for 1,2-addition for standard organometallic (and other) nucleophiles suggests something unique about 1,4-addition of organocuprates



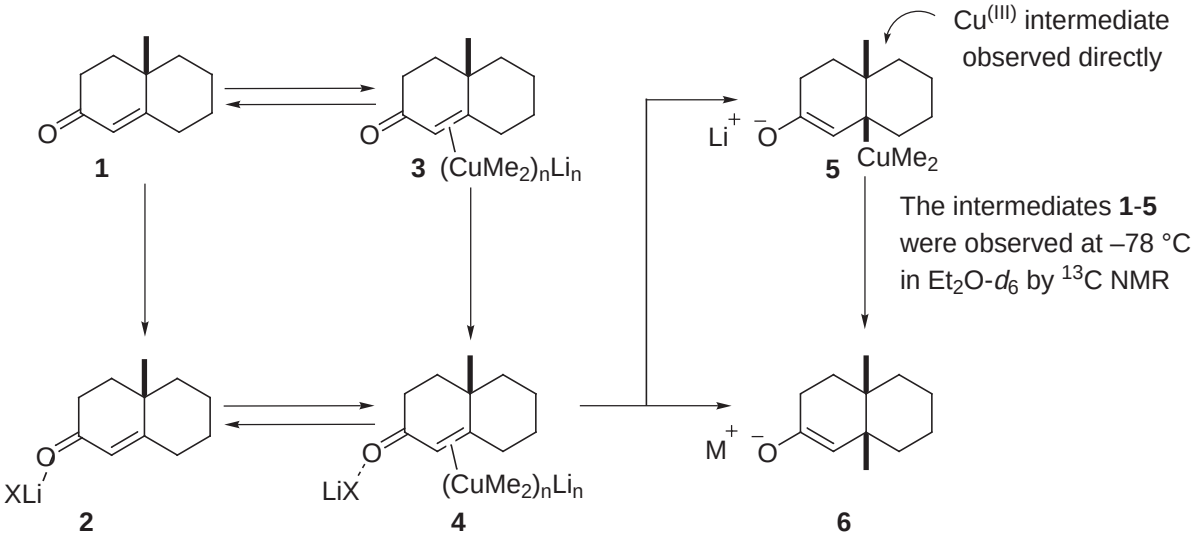
R-M



R-CuX

vii. ^{13}C NMR detection of reaction intermediates

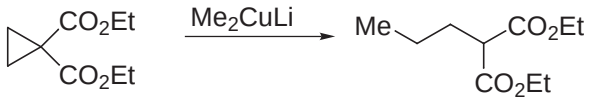
- Mechanism of organocuprate conjugate addition: observation of cuprate-olefin complexes and Li-coordinated intermediates in the reaction of lithium dimethyl cuprate with 10-methyl-$\Delta^{1,9}$-2-octalone. Robin and Smith *J. Am. Chem. Soc*, **1989**, *111*, 8276.



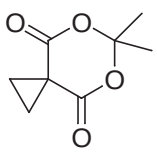
See also: Corey *Tetrahedron Lett.* **1990**, *31*, 1393.

viii. Isolation of the π-complex and conversion on to product
Corey *Tetrahedron Lett.* **1985**, *26*, 6015.

3. Homoconjugate Addition

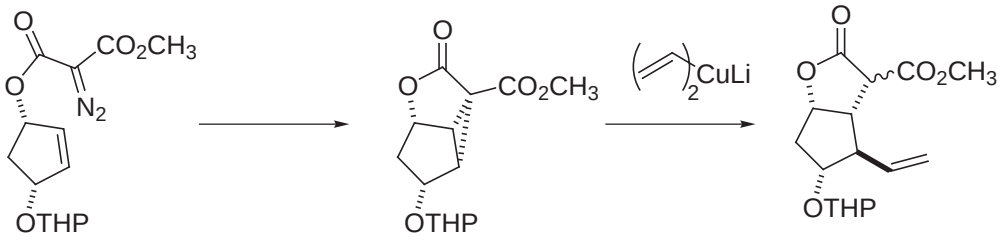


- Can also use



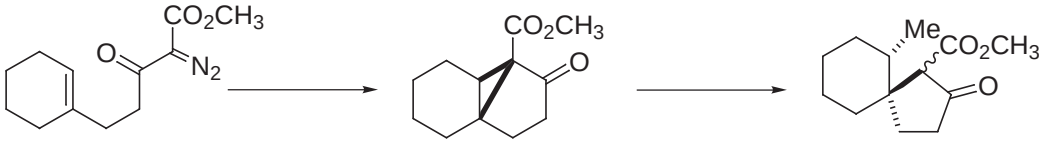
-These reactions work well with Me_2CuLi, and probably vinyl cuprates and aryl cuprates (no problem with β elimination) but not as well for simple alkyl cuprates (less stable-must keep < –30 °C)

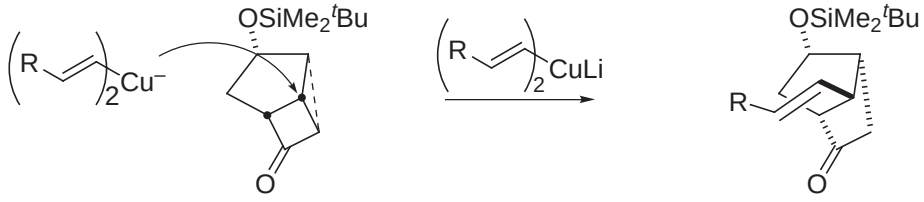
- Application to prostaglandin synthesis:



Corey *J. Am Chem. Soc.* **1972**, *94*, 4014.

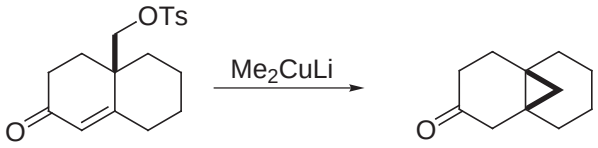
and



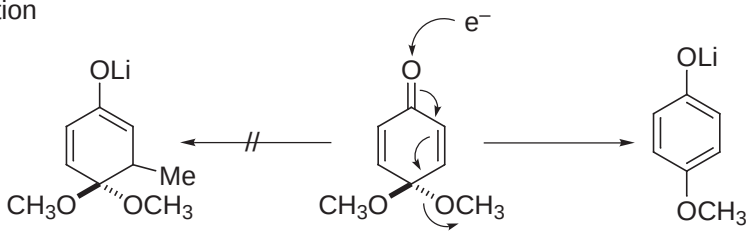


4. Competitive Reduction and Rearrangement

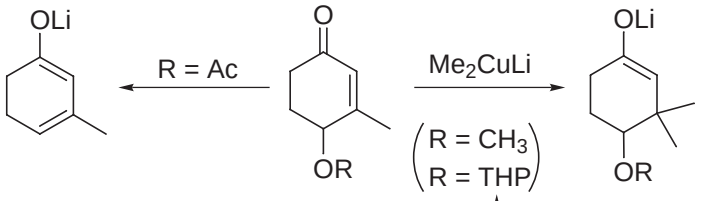
a) Interception of radical-anion intermediate



b) Reduction



Also observed with γ-acyloxy enones:

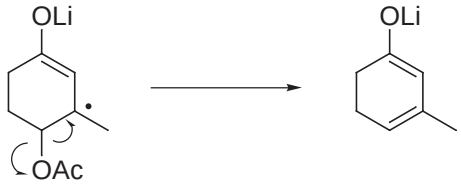


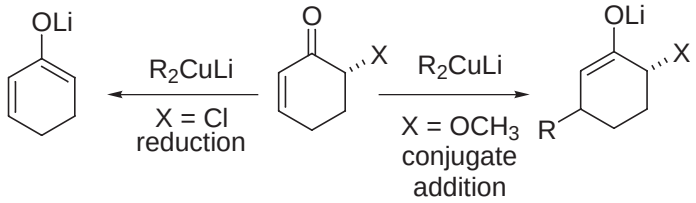
Ruden *Tetrahedron Lett.* **1975**, 2043.

poorer leaving groups

Note: This is cited as further support of the electron transfer mechanism.

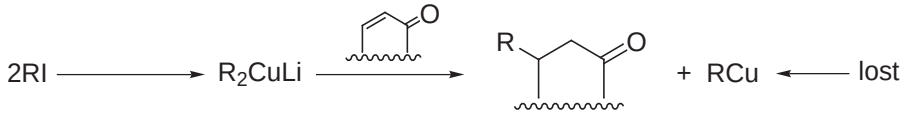
via



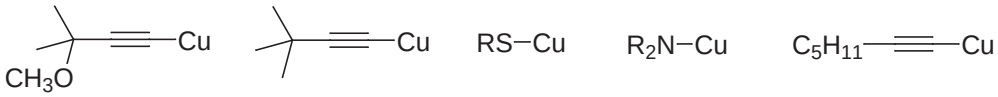


5. Mixed Organocuprates

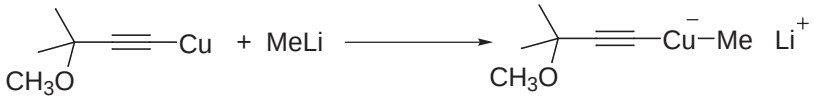
- For dialkylcuprates, one alkyl substituent (ligand) is lost:



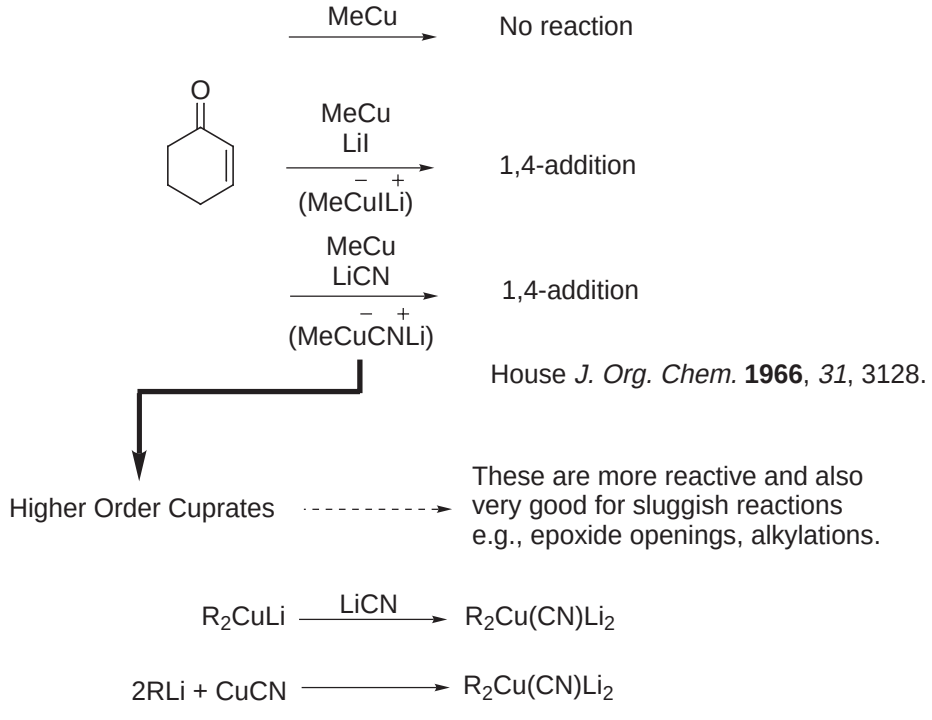
- Mixed cuprates have been developed in which one ligand will not transfer:
  Corey *J. Org. Chem.* **1978**, *43*, 3419.



- With these reagents, only the non-transferable reagent is lost



- Also: addition of Li salts forms cuprate reagents from alkyl copper reagents ("ate" complexes)



See: Lipshutz *Org. React.* **1992**, *41*, 135.
Lipshutz *Synthesis* **1987**, 325.

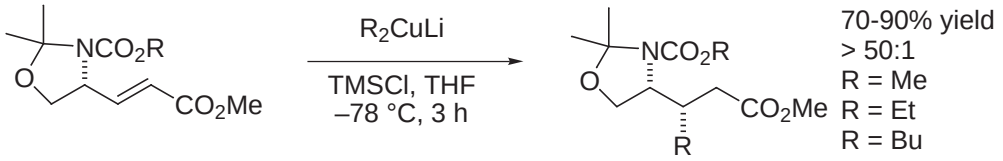
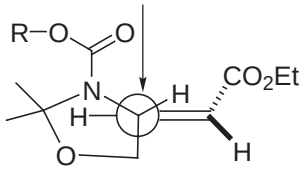
- favorable interaction between alkoxy and π system.
- free of 1,2-allylic strain.
- increased stabilization of the α,β-unsaturated system via interaction between low-level π* orbital and high-level σR' - C orbital..





- favorable interaction between parallel σC - R and σ*C - Cu orbitals.
- possibility of chelation between carbamate and ester may overide 1,2-allylic strain as well as bulk of γ-substituent.

Stereochemistry of Organocuprate Conjugate Addition Reactions (References)

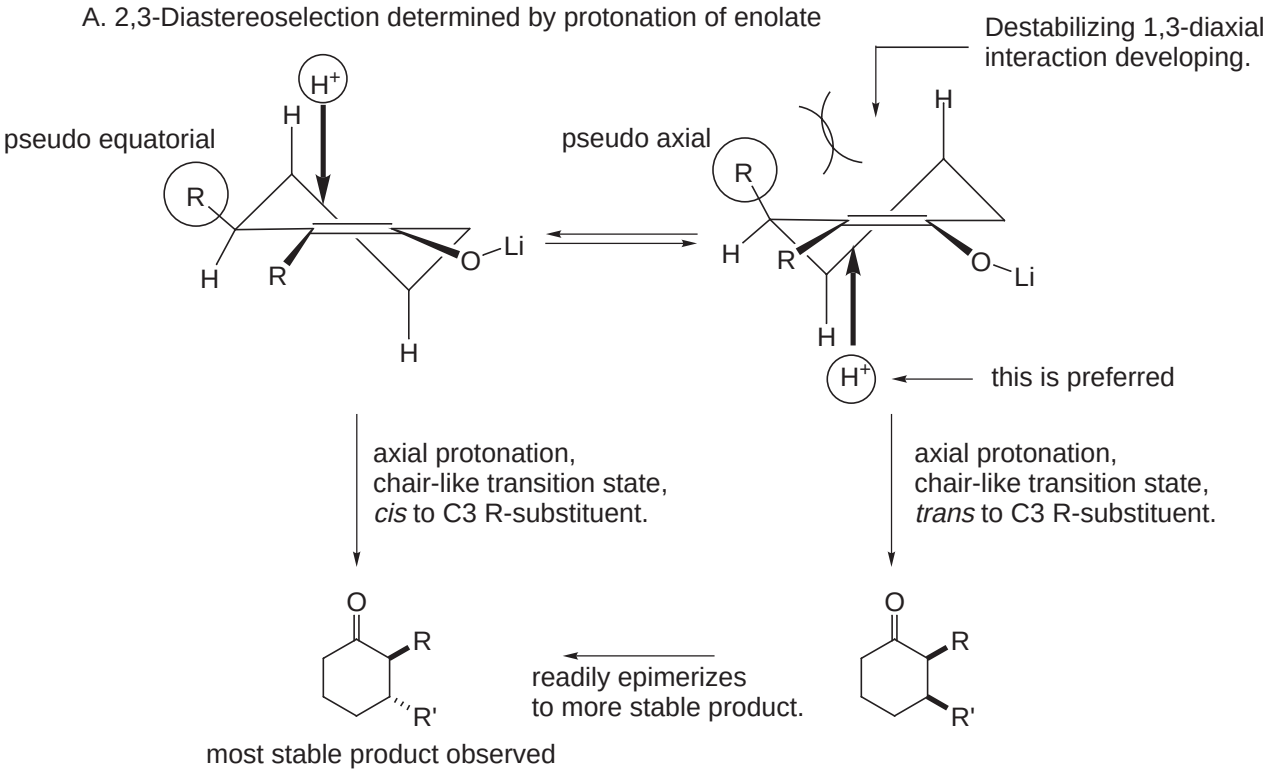
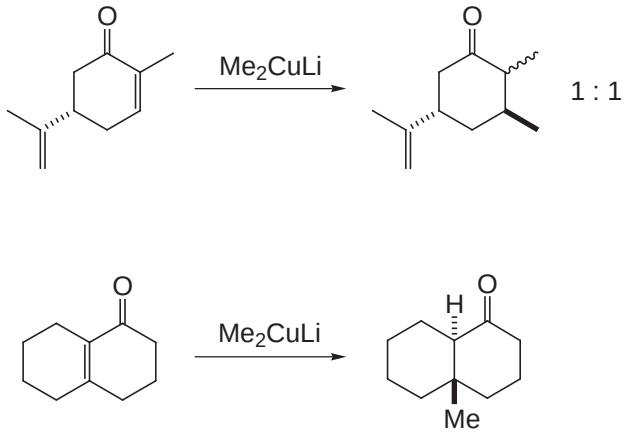
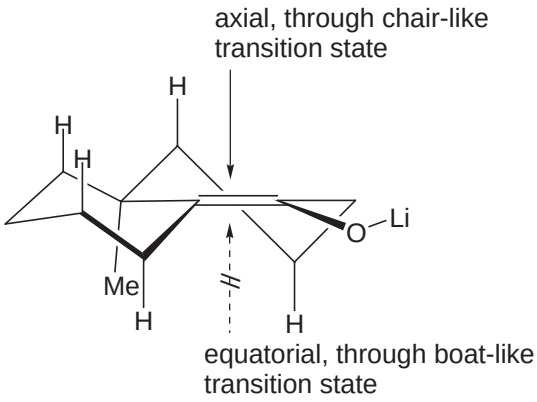
8. Origin of Diastereoselectivity



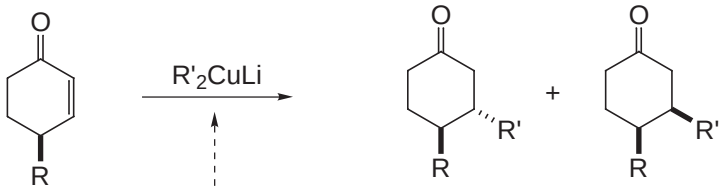
- Examples:





Posner *J. Org. Chem.* **1973**, *38*, 4459.

B. 3,4-Diastereoselection



R = Me	R'	Ratio	
	Me	72:28	
	Et	78:22	
	^{i}Pr	88:12	
	Ph	87:13	(75%)
		96:4	(PhCu)

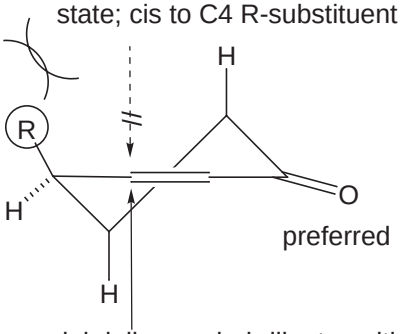
increasing size of R'
increasing amount of *trans*

R = Et	R'	Ratio
	Me	77:23
	Et	89:11

increasing size of R
increasing amount of *trans*

R = ^{i}Pr	R'	Ratio
	Me	89:11
	Et	92:8

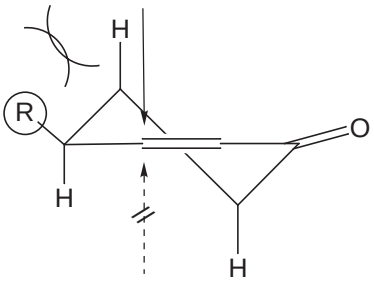
equatorial delivery, boat-like transition state; cis to C4 R-substituent



preferred

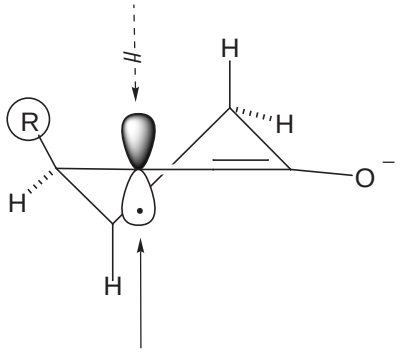
vs.

axial delivery, chair-like transition state; cis to C4 R-substituent

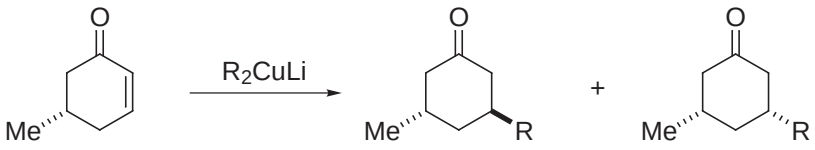


axial delivery, chair-like transition state; trans to C4 R-substituent

but remember: reactive intermediate is radical anion



C. 3,5-Diastereoselectivity



trans (major) *cis* (minor)

House *J. Org. Chem.* **1968**, *33*, 949.

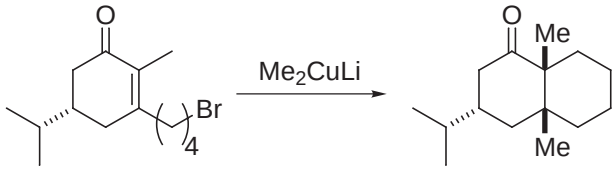
R = Me	93	:	7	(MeMgI, cat, CuI) >90%
	98	:	2	(Me_2CuLi)
	99	:	1	(Me_2CuLi + LiI)

Posner *J. Am. Chem. Soc.* **1975**, *97*, 107.

R = CH_2Ar *trans* only

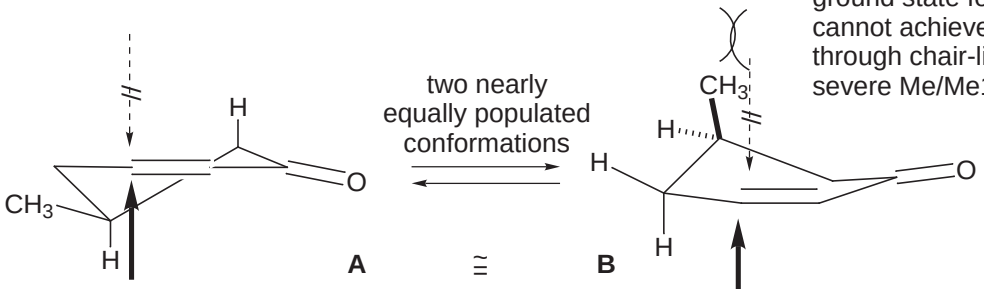
unaffected by C-3 substitution

Posner *J. Am. Chem. Soc.* **1975**, 97, 107.



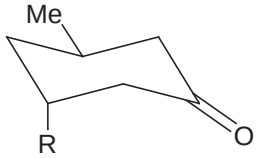
- equatorial delivery of group, grows into boat conformation of enolate.

no destabilizing interactions in the ground state for axial Me group but cannot achieve axial delivery of Nu^- through chair-like transition state: severe Me/Me1,3-diaxial interaction.



axial delivery of group grows into chair form of enolate

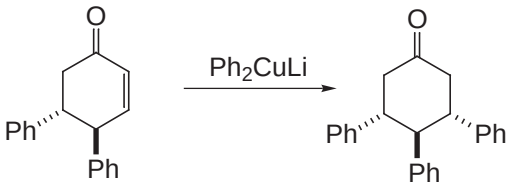
equatorial delivery but would grow into boat conformation of enolate

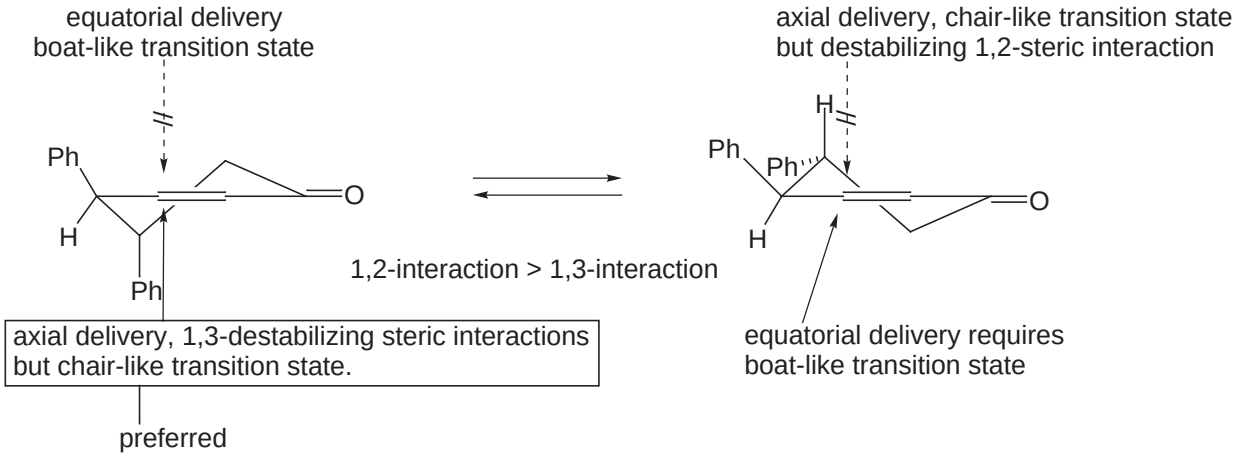


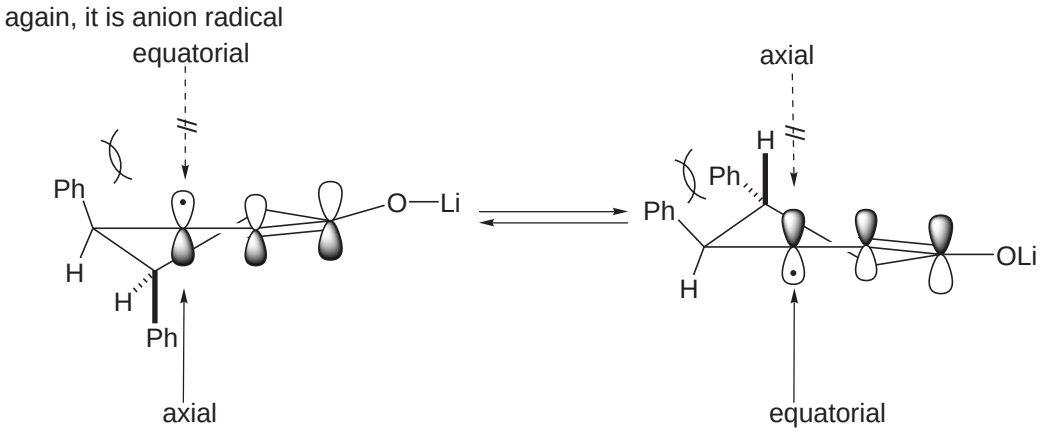
enone with alkyl substituent in the equatorial position is the reactive conformation.

D. 3,4- vs 3,5-Diastereoselectivity

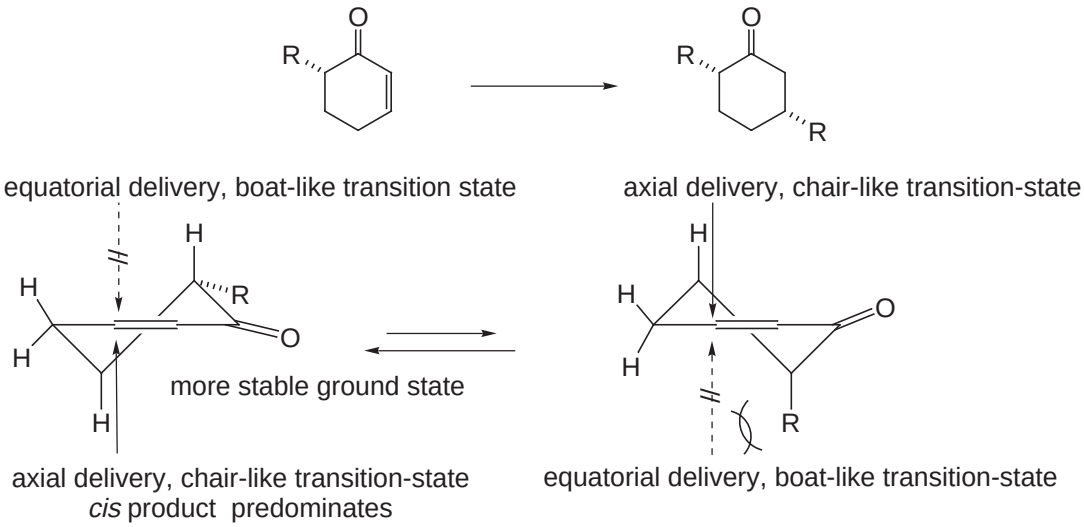
3,4 > 3,5





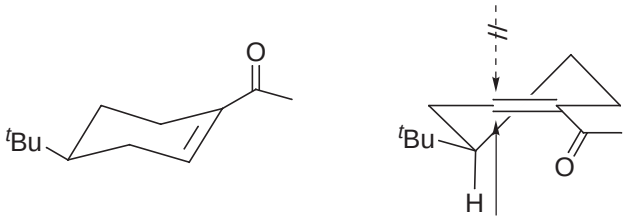


E. 3,6-Diastereoselectivity



F. Exocyclic enones

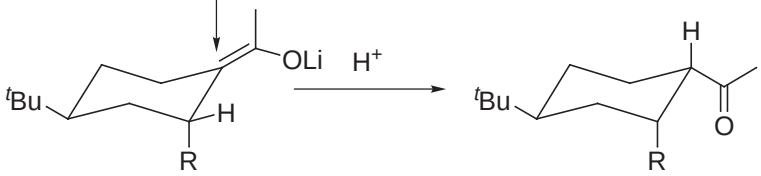
equatorial attack would require
boat-like transition state



axial attack proceeds through
chair-like transition state

axial protonation

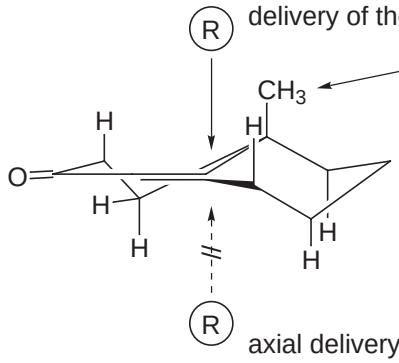
(observed even when ^{t}Bu replaced with H,
see alkylation section).



G. Fused enones

relative to B ring this is equatorial
delivery of the nucleophile.

decelerates conjugate addition
this steric interaction is a
1,2-interaction or torsional strain (eclipsing interaction)

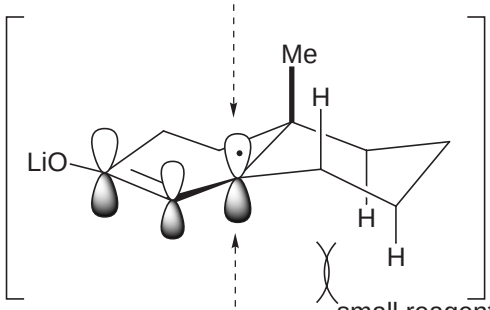


Cuprate behaves as large nucleophile preferring
equatorial attack (1,2-interactions) to axial attack
(1,3-interactions) on the exocyclic olefin.

axial delivery of nucleophile suffers
severe steric interactions (1,3-diaxial interactions)

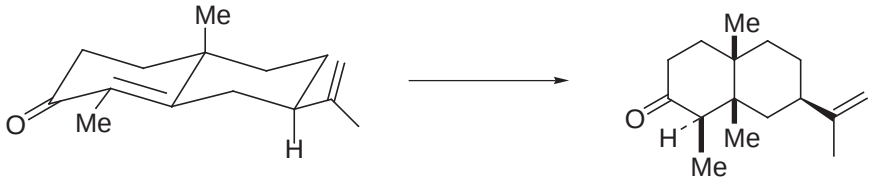
-May really want to consider radical-anion conformation

1,2-torsional interaction
large reagent (Cuprate)



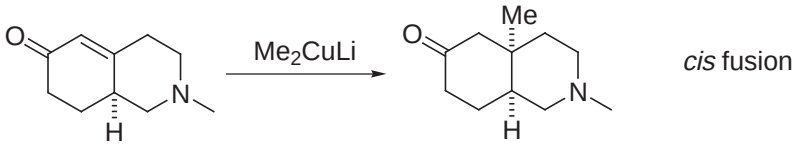
small reagent (H^+)
(e.g., Birch reduction)

1,3-steric interactions

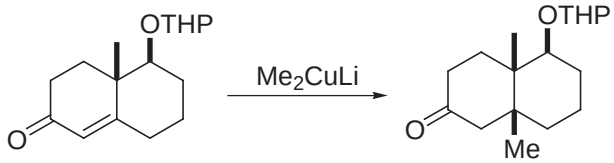


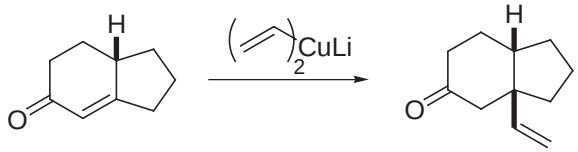
- *cis* ring fusion.
- protonation from least hindered face of enolate, also most stable product.

Piers *Can. J. Chem.* **1969**, *47*, 137.



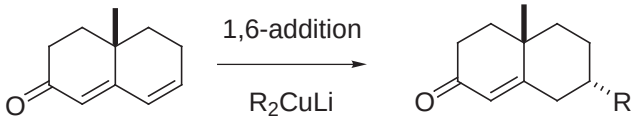
cis fusion



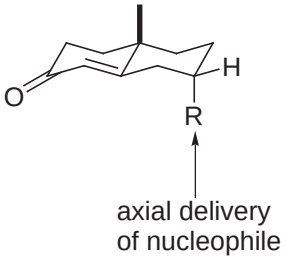


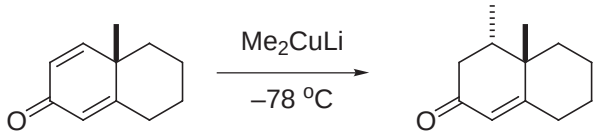
Corey *J. Am Chem. Soc.* **1971**, *93*, 7318.

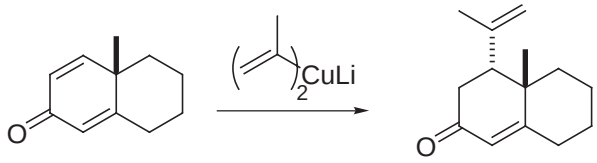
- but



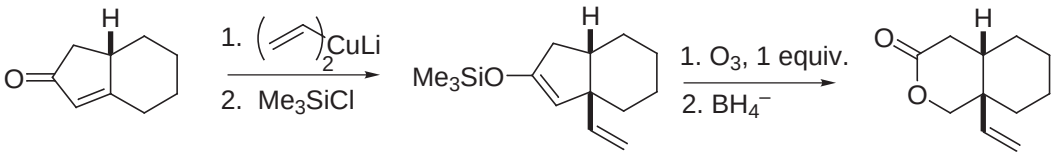
R = Me	93:7
Et	98:2
*i*Pr	100:0
*t*Bu	100:0







96%



74% 80%

Angew. Chem., Int. Ed. Eng. **1991**, *30*, 455. (Nobel Prize Lecture)

E. J. Corey received the 1990 Nobel Prize in Chemistry for his development of the theory and methodology of organic synthesis. His development and systemization of retrosynthetic analysis transformed organic synthesis from inspired recognition of a route into a precise and logical science. As the modern techniques of structure determination emerged (NMR, IR, X-ray), Corey applied his retrosynthetic analysis to some of the most challenging syntheses of the time. The application of computer analysis with LHASA (Logic and Heuristics Applied to Synthetic Analysis), the development of practical synthetic methodology for individual transformations based on clear mechanistic rationales, and the more than 100 natural product total syntheses that followed transformed modern organic synthesis.

Corey, Cheng *The Logic of Chemical Synthesis*, Wiley: New York, 1989.

A. Classifications

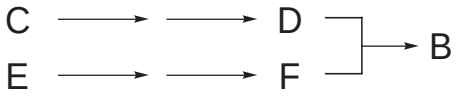
1. Linear Synthesis

- The target compound is made through a series of linear transformations.

5-steps	overall yield
90%/step	59%
70%/step	17%

2. Convergent Synthesis

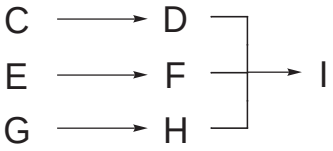
- Individually prepared compounds are convergently brought together to make the target compound.



5-steps	overall yield
90%/step	73%
70%/step	34%

Advantages of a convergent synthesis
- shorter
- simpler to execute
- higher overall yields
- better material balance and supply

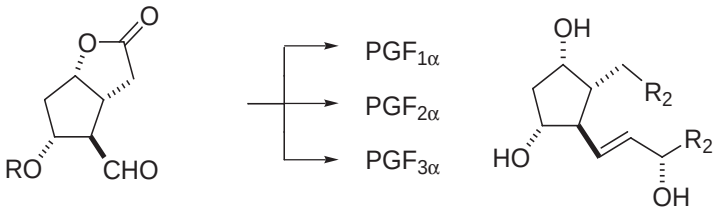
- Triply Convergent Synthesis
  -three major components are brought together in a single step to make the target compound.



3. Divergent Synthesis

- For a class of compounds, it is advantageous to prepare a common intermediate and use this common intermediate to prepare all members of the class of agents.

- Examples: prostaglandins

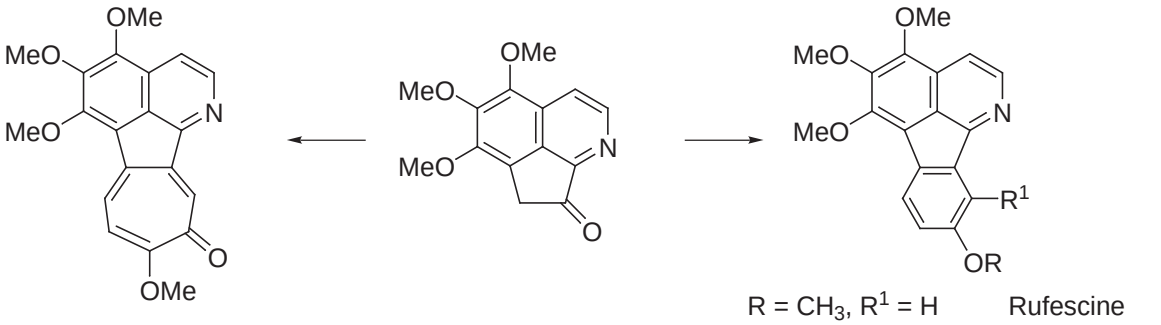


Variations lie only
in the side chains

- Rather than use a linear synthesis for all agents, a divergent synthesis allows the use of a common intermediate to prepare structurally related products.
- The divergent synthesis is a very good strategy if structure-activity studies are the ultimate goal.

Note: Though widely used, the discussion of this strategy was first formally presented in the literature along with a disclosure of a strategy for divergent aromatic annulation in conjunction with the total synthesis of a series of azafluoranthene alkaloids. Today, the divergent introduction of diversity is the basis of most combinatorial chemistry methods.

Boger *J. Org. Chem.* **1984**, *49*, 4050; see also *J. Org. Chem.* **1984**, *49*, 4033 and 4045.



Imerubrine

R = CH_3, R^1 = H	Rufescine
R = H, R^1 = H	Norrafescine
R = CH_3, R^1 = OCH_3	Imeluteine

Boger *J. Am. Chem. Soc.* **1995,** *117*, 12452.

Boger *J. Org. Chem.* **1984,** *49*, 4050.

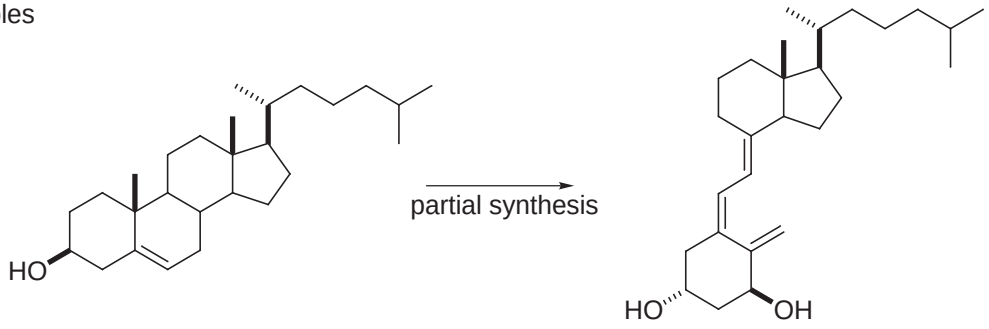
4. Total Synthesis

- Start with readily available materials and build up to the target molecule from simple, common materials.

5. Partial Synthesis

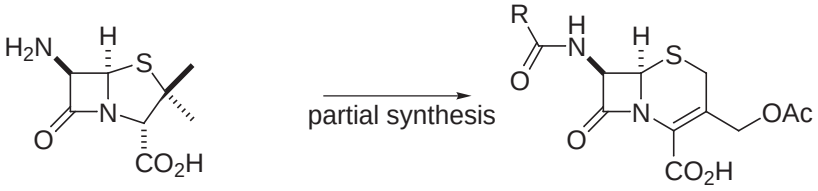
- This is technically not a total synthesis.
- Start with a naturally occurring compound or an advanced intermediate and independently convert that to the target molecule.

- Examples



Previtamin D_3

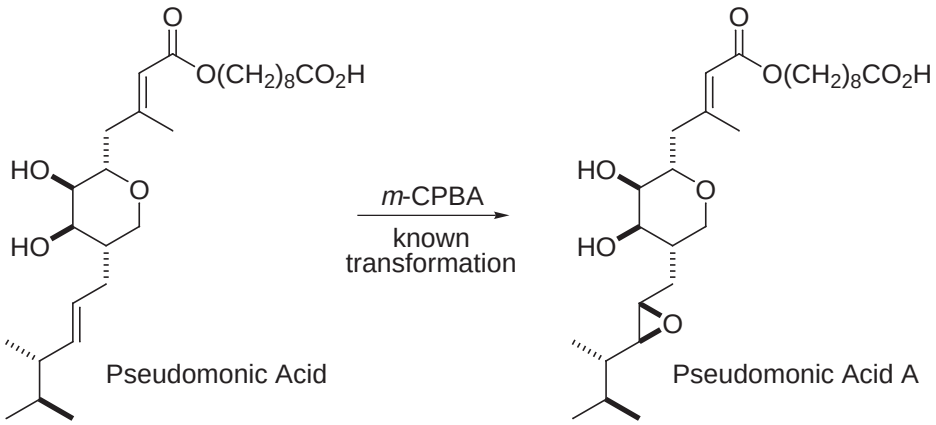
- For commercialization, it would be hard to match the synthesis starting with cholesterol.



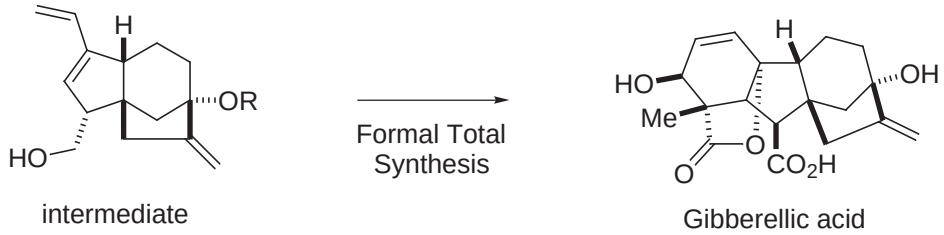
Penicillins, available by fermentation at Lilly, as an inexpensive bulk chemical

Cephalosporins - not as accessible through fermentation

6. Formal Total Synthesis vs. Total Synthesis



Rogers *Tetrahedron Lett.* **1980,** 881.
Kozikowski *J. Am. Chem. Soc.* **1980**, *102*, 6577.



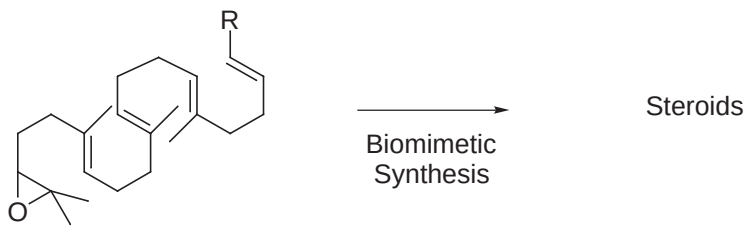
Independent synthesis of this precursor would constitute a formal total synthesis of gibberellic acid since the conversions have been previously accomplished. In this case, the key intermediate is so far from the final target that most would not "claim" such an accomplishment unless the final conversions were also developed within their own laboratories.

7. Biomimetic (Total) Synthesis

- Presumably, nature will not be using a process that is intrinsically difficult or impossible. It is believed that one can effectively mimic the conditions provided by nature, and conduct the same reaction in a flask.

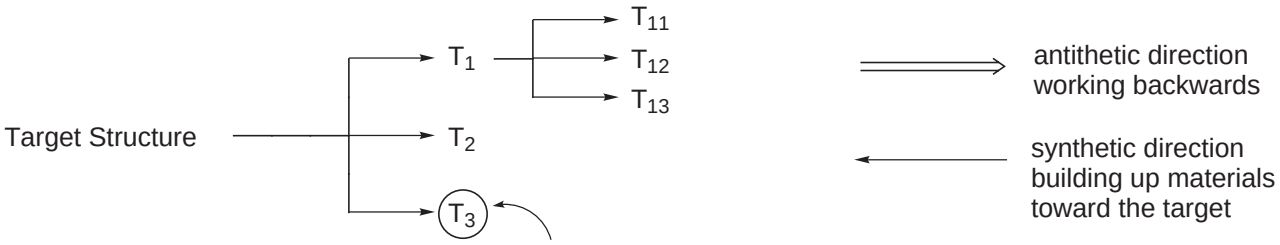
- Two important considerations
  1 - The reaction must be capable of occurring
  2 - The biogenetic process is under a great deal of control (enzymatic) and a similar level of control in lab may be difficult, but necessary

- Classic example : Steroid synthesis
  Extensively studied and many good chemists failed before the experimental parameters were sufficiently defined to mimic the cation-olefin cyclization.



B. Retrosynthetic Analysis

- Work backwards from the target compound to generate a set of intermediates which can be made from available starting materials.



These less complicated building blocks in organic synthesis were called synthons in the early years. Now they are referred to as retrons.

Objectives:

1. Generate a large number of potential approaches in order to obtain an optimal route.
2. Strive to generate simpler, less complex intermediates which can be obtained from readily available materials.
3. All steps are subject to reevaluation - this allows for design of a better or optimized synthesis.

Steps in Design and Execution of a Synthesis

1. Selection of a problem
2. Selection of goals to be achieved through synthesis
3. Simplification
4. Generation of synthetic pathways
5. Evaluation of synthetic pathways --> assignment of merit
6. Selection of specific reactions and reagents for each step
7. Selection of specific reaction conditions and design of experiments
8. Execution and analysis of results

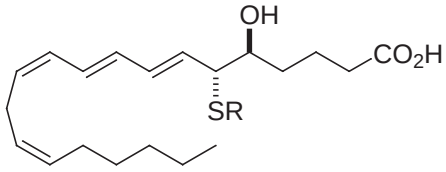
more time is or should be devoted to steps 1 and 2 than most may realize

steps 3 and 4 constitute retrosynthetic analysis

Because of the amount of time and effort involved in the execution, it is important to be meticulous in evaluating the potential synthetic pathways.

1. Selection of a problem
   - One of the most important considerations.
   - Should be the first consideration, independent of all others. This assures that it is a problem that you want to address.
   - Recognize the time and effort involved in the actual conduct of the synthesis.
   - This will depend on the setting, circumstances and interests of the individual.

2. Selection of goals



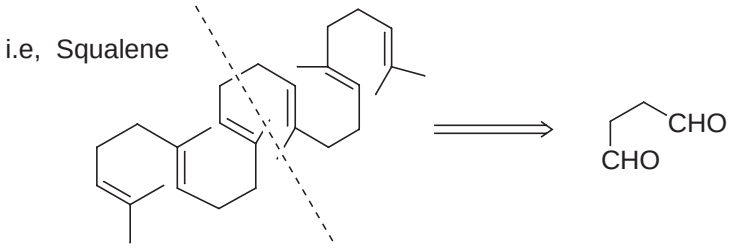
SRS-A (Slow Reacting Substance of Anaphylaxis)

a. Structure determination of SRS-A: the initial intent. The R group on the thiol was not known, so the first synthesis was designed to facilitate the introduction of different R groups permitting a comparison with the endogenous product to confirm the structure.
b. Once the structure was determined, objectives included providing sufficient material for biological testing.
c. Determination of absolute configuration - the chiral centers were unambiguously established through synthesis.
d. Development of a route amenable to analogue preparation: want to inhibit the action of SRS-A (an antagonist development).
e. Biomimetic synthesis (follows the biosynthetic generation of materials) - might constitute a simplification.

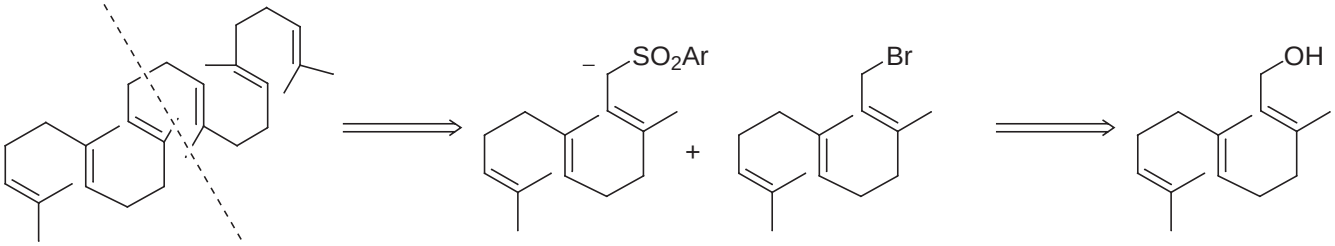
f. Development of commercially viable processes.
g. Demonstration of improvements in current methodology.
h. Novel, interesting structures.
i. Common intermediate for a class of structures (divergent synthesis).
j. Mechanism of action of a class of compounds - devise partial structures of the parent . compound to define the mechanism of action.
k. Chemistry of a class of compounds.
l. Properties of a class of compounds.

> The specific goals are established prior to the generation of the retrosynthetic pathway. The goals will play an important role in the assignment of relative merit of each potential pathway in the retrosynthetic analysis.

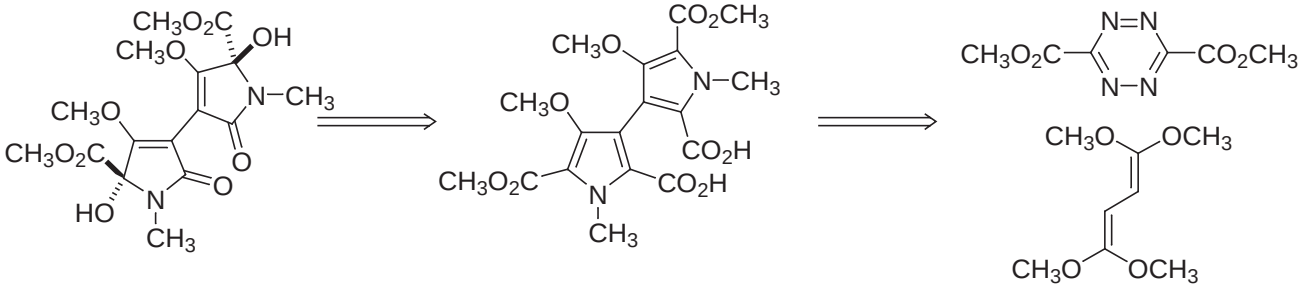
3. Simplification and Background Chemistry
   a. Recognition of symmetry elements present in a structure.



- two identical halves
- build out from a central core by conducting each of the steps twice and simultaneously
- Johnson *J. Am. Chem. Soc.* **1970**, *92*, 741.



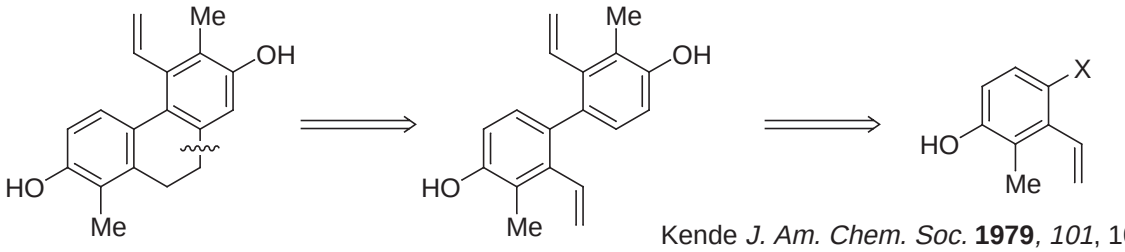
- combines two halves prepared from a common intermediate at the end of the synthesis.
- Grieco *J. Org. Chem.* **1974**, *39,* 2135.



Isochrysohermidin Boger *J. Am. Chem. Soc.* **1993**, *115*, 11418.

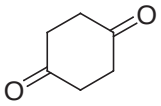
- The recognition of symmetry elements is not always so obvious by initial examination of the agent.

e.g., Juncusol



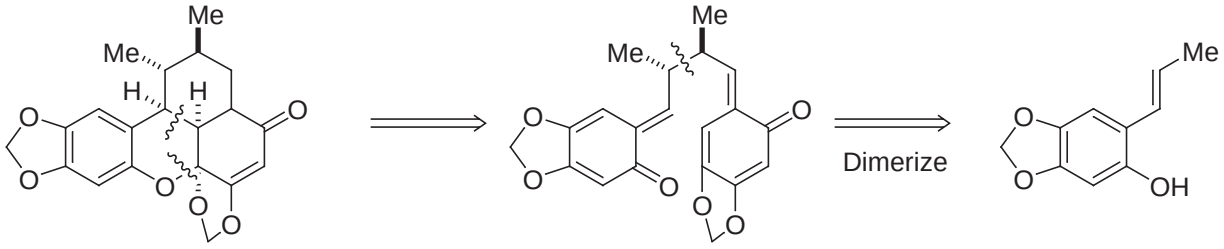
Kende *J. Am. Chem. Soc.* **1979**, *101*, 1057.

now symmetrical - simplification
of the synthetic problem



or start with the central ring and build out in a similar symmetrical fashion
Boger *J. Org. Chem.* **1984**, *49*, 4045.

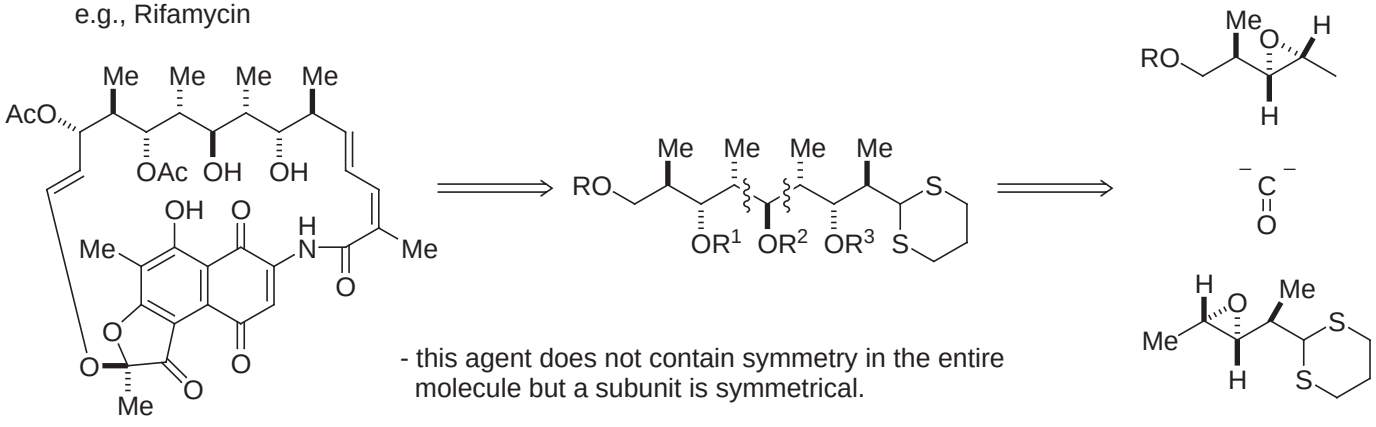
e.g., Carpanone



Chapman *J. Am. Chem. Soc.* **1971**, *93*, 6696.

- biomimetic synthesis of this agent allows for simplification.
- this is a very good example where the symmetry elements are not obvious by looking at the agent.

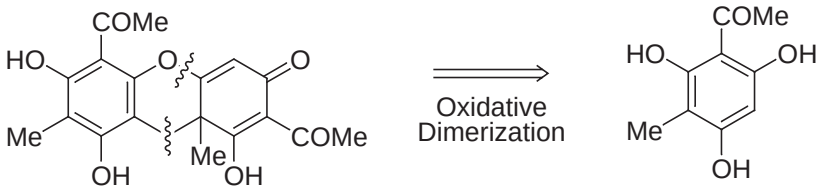
e.g., Rifamycin



- this agent does not contain symmetry in the entire molecule but a subunit is symmetrical.

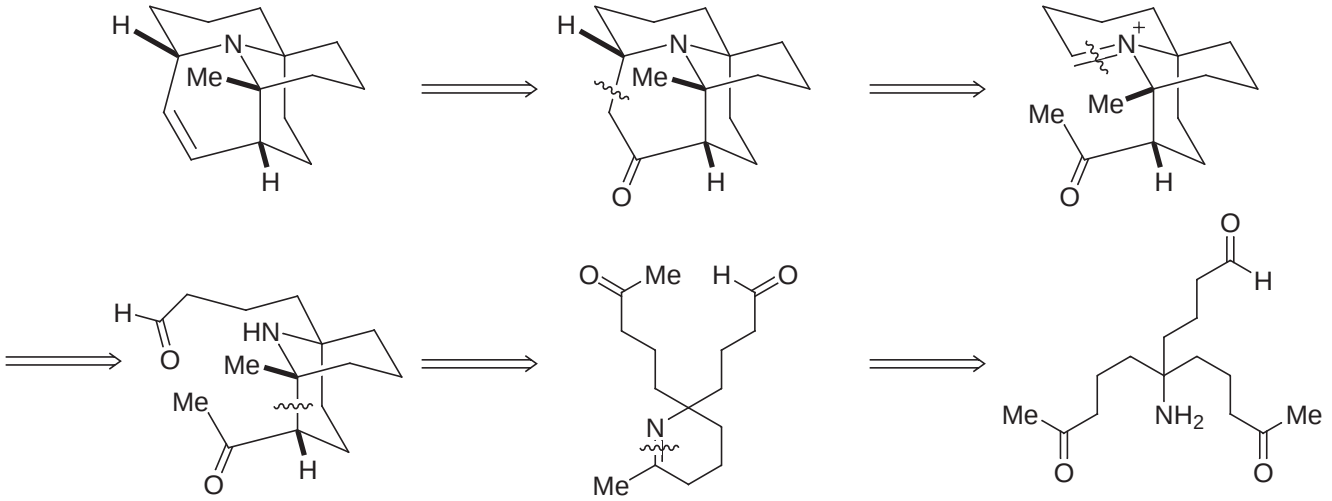
Corey *Tetrahedron Lett.* **1979**, 335.

e.g., Usnic Acid



Barton *J. Chem. Soc.* **1956**, 530.

e.g., Porantherine

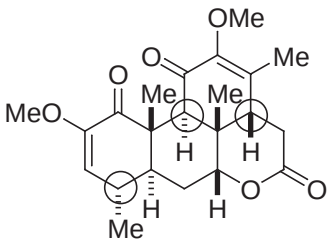


Corey *J. Am. Chem. Soc.* **1974**, *96*, 6516.

- the symmetry elements are tucked more deeply into the structure

b. Background Chemistry
- Information available in the literature will provide very important insights required to effectively design a synthesis.

e.g., Quassin

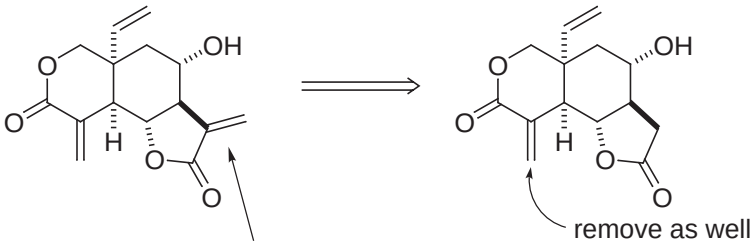


Grieco *J. Am. Chem. Soc.* **1980**, *102*, 7586.

- 7 stereocenters but 3 are epimerizable centers and the natural product possesses the most stable configuration, so a synthesis without stereocontrol of these 3 centers can be used (epimerize later). Need only worry about control of 4 of the 7 stereocenters.

c. Recognize and Remove Reactive Functionality
- Another key to simplification derived from background chemistry

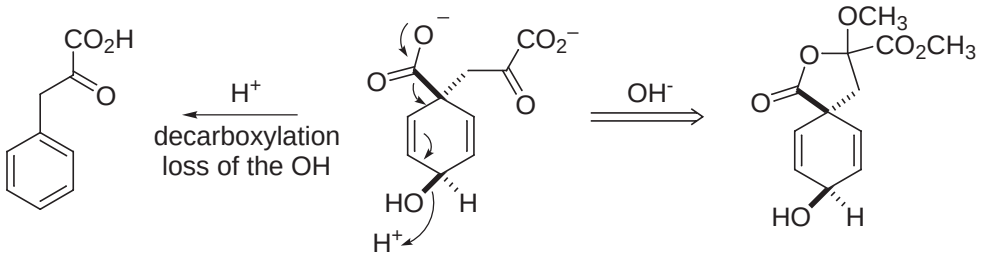
e.g., Vernolepin



- α-Methylene lactone in a *trans*-fused 5-membered ring
  This is extraordinarily reactive to nucleophiles (Michael).
  It will not stand up to many synthetic steps/reagents.
- the final step should be introduction of the reactive group.

Danishefsky *J. Am. Chem. Soc.* **1976**, *98*, 3028.
Grieco *J. Am. Chem. Soc.* **1976**, *98*, 1612.
Danishefsky *J. Am. Chem. Soc.* **1977**, *99*, 6066.

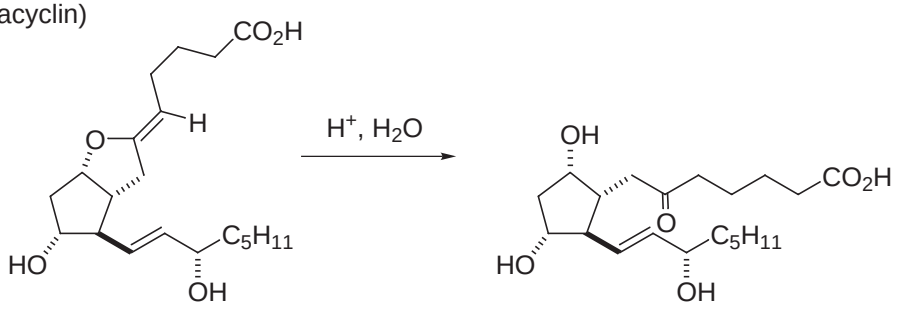
e.g., Precursor to aromatic amino acids



- acid sensitive (derived from background chemistry).
- a successful approach must involve generation
  under basic conditions.

Danishefsky *J. Am. Chem. Soc.* **1977**, *99*, 7740.

e.g., PGI_2 (prostacyclin)



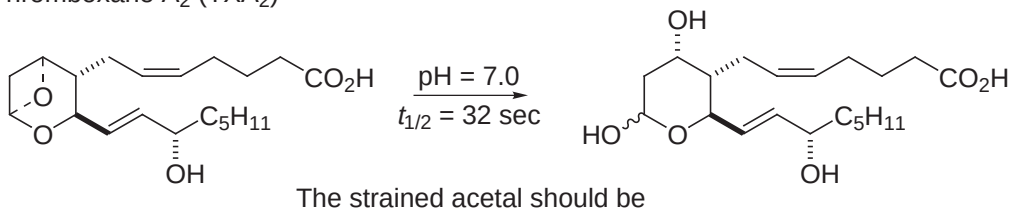
- enol ether sensitive to acid-catalyzed hydrolysis.

Corey *J. Am. Chem. Soc.* **1977**, *99*, 2006.

U. von Euler received the 1970 Nobel Prize in Medicine for the discovery of hormonal transmitters in the nerve terminals and the mechanism for their storage, release, and inactivation.

S. K. Samuelsson and J. R. Vane shared the 1982 Nobel Prize in Medicine for their discovery of the prostaglandins and related biologically active substances.

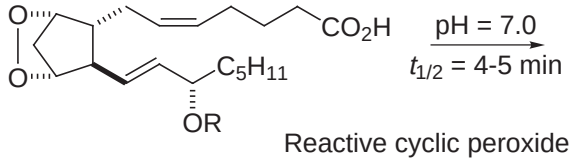
e.g., Thromboxane A_2 (TXA_2)



The strained acetal should be introduced late in the synthesis

Still *J. Am. Chem. Soc.* **1985**, *107*, 6372.

e.g., PGH_2 (R = H)
PGG_2 (R = OH)

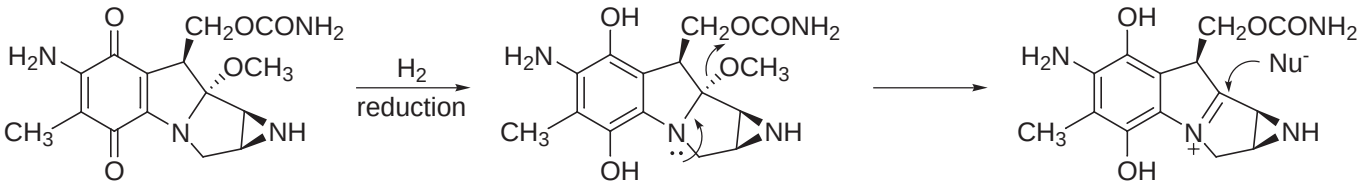


Reduction / Acid-catalyzed Rearrangement

Reactive cyclic peroxide is sensitive to nucleophilic attack - introduce late in the synthesis

Porter *J. Am. Chem. Soc.* **1980**, *102*, 1183.
Salomon *J. Am. Chem. Soc.* **1979**, *101*, 4290.
Porter *J. Am. Chem. Soc.* **1979**, *101,* 4319.

e.g., Mitomycin C - stable as the quinone



note vinylogous amide

hydroquinone - basic, nucleophilic
free amine - intermediate less stable

steer clear of such synthetic intermediates

There are only two total syntheses of mitomycin C to date

Kishi *J. Am. Chem. Soc.* **1977**, *99*, 8115.
Fukuyama *J. Am. Chem. Soc.* **1989**, *111*, 8303.

Absolute configuration established in *J. Am. Chem. Soc.* **1967**, *89*, 2905 by a single crystal X-ray structure (INCORRECT).

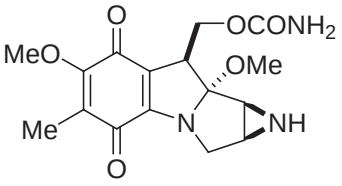
But in the early 1980's, additional X-ray structures on related agents gave the opposite and correct absolute configuration. Take home message: Evaluate the quality of the background chemistry and assess the level of confidence and committment you want to place on it. The earlier X-ray was not on a heavy atom derivative and preceded the advances in direct methods we take for granted today.

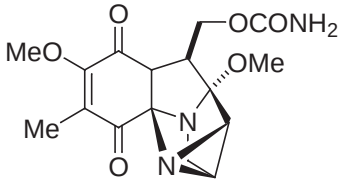
Hirayama *J. Am. Chem. Soc.* **1983**, *105*, 7199.

A number of Nobel Prizes have chronicled the achievements of X-ray crystallography including the contributions of:

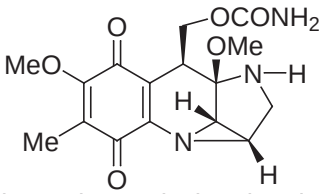
J. Kendrew and M. Perutz (1962, heavy atoms and structure of hemoglobin).
D Hodgkin (1964, X-ray structure determinations including vitamin B-12, penicillin and insulin).
O. Hassel (1969, chair conformation of cyclohexane reported in 1930).
W. N. Lipscomb (1976, borane structures and chemical bonding).
A. Klug (1982, elucidation of nucleic acid-protein complexes).
H. A. Hauptman and J. Karle (1985, direct methods).

- The background chemistry can provide keys to the design of a synthetic strategy.



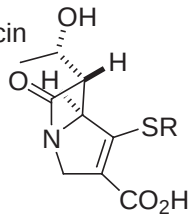


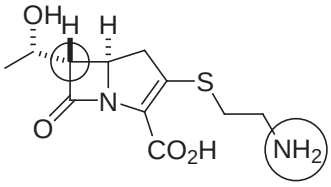
Mitomycin Rearrangement

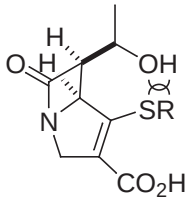


Isomitomycin was isolated and characterized and provided the basis for Fukuyama's total synthesis.

e.g., Thienamycin







trans preferred

cis less favored

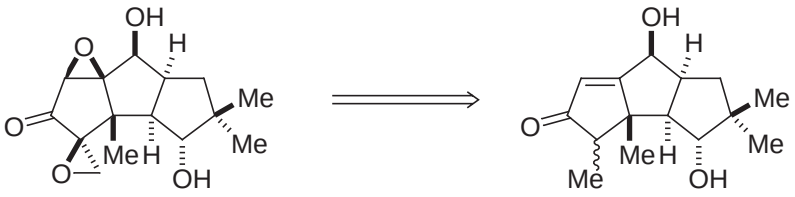
must protect the amine throughout the synthesis.
unusual *trans* H-H relationship - easily epimerizable center and fortunately, *trans* is most stable configuration.

A. Fleming and H. W. Florey received the 1945 Nobel Prize in Medicine for the discovery of penicillin and its curative effects in various infectious diseases.

Grieco *J. Am. Chem. Soc.* **1984**, *106*, 6414.
Georg *J. Am. Chem. Soc.* **1987**, *109*, 1129.

Yet - almost all the early syntheses went to great length to control this relative stereochemistry and it often, unnecessarily, added to their length.

e.g., Coriolin



introduce reactive functionality last

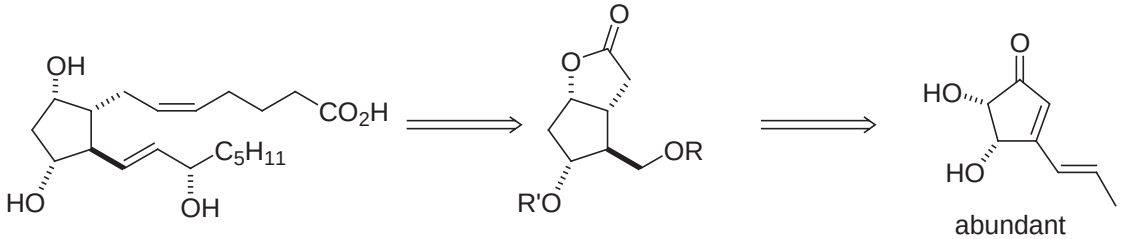
Danishefsky *J. Am. Chem. Soc.* **1981**, *103*, 3460.

4. Generation of Synthetic Pathways (Retrosynthesis) (General strategies employed in working backwards)
Covered in detail in Corey *The Logic of Chemical Synthesis*, Wiley: New York, 1989, pp. 1-98.

a. Transform-based strategies
- powerful, simplifying transformation that reduces complexity.
- usually very key reactions in the synthesis that dominate the approach - formation of a key intermediate (i.e., the Diels-Alder transform, the aldol transform).

b. Structure-goal strategies
- oldest approach.
- in working backwards from the target molecule to the various intermediates, an intermediate may actually be located that is already in the literature or commercially available.

e.g., Prostaglandins



abundant

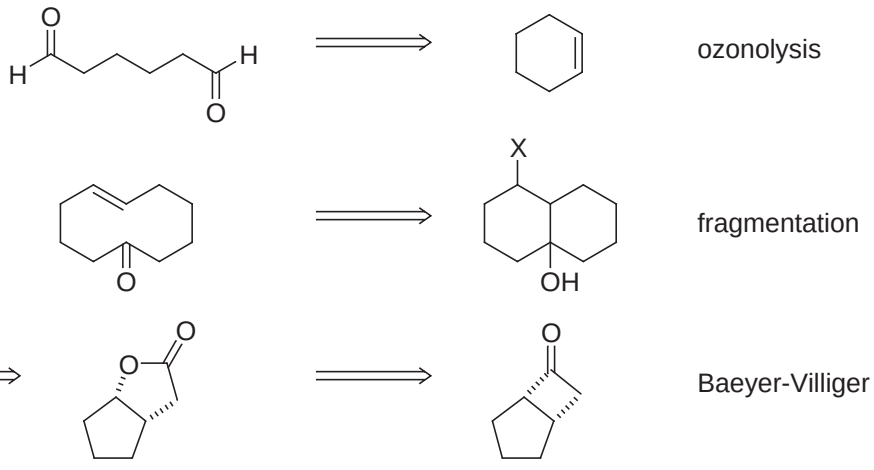
c. Topological strategies
- strategic bond disconnections (*J. Am. Chem. Soc.* **1975**, *97,* 6116).
- recognize strategic bonds and remove them in the retrosynthetic direction.

d. Stereochemical strategies
- strategies which remove the stereocenters.
- simplifying the stereochemistry of the product may be related to:
  1. substrate - features of the substrate will permit you to solve the stereochemical problems.
  2. mechanism - reaction mechanism will permit relative or absolute stereocontrol.

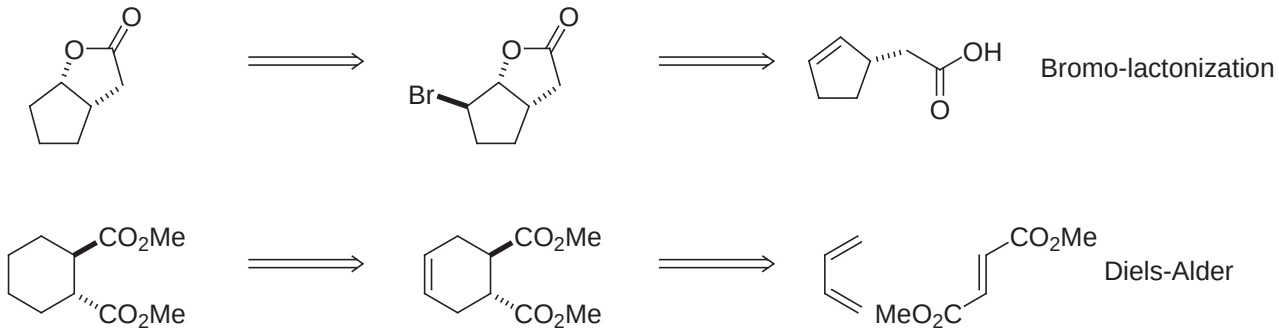
e. Functional group strategies

1. Functional group interconversion (FGI)
   - don't gain much but it permits you to get from one point to another.

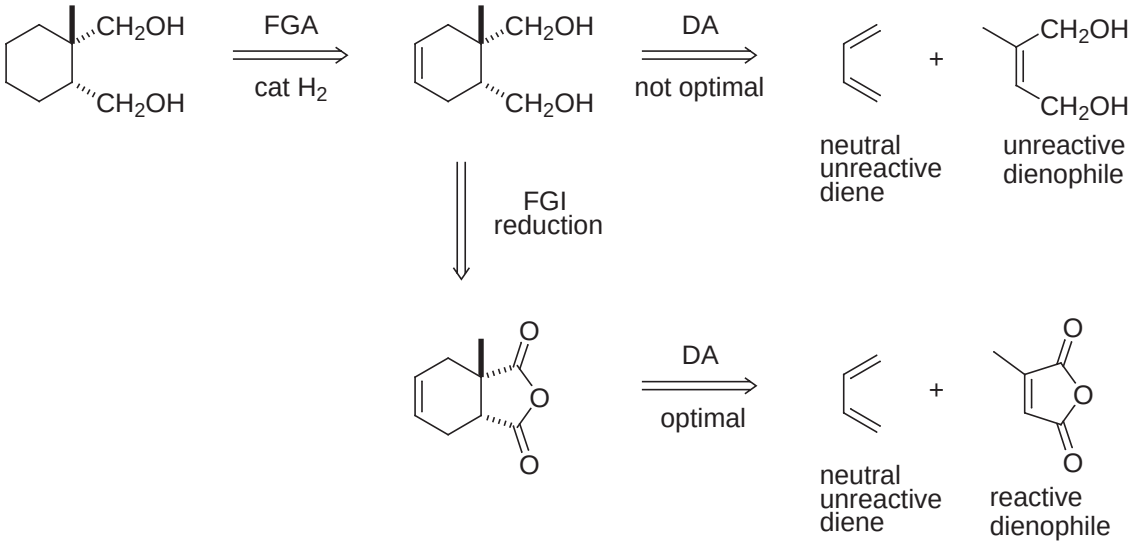
2. Functional group combination (FGC)
   - combine pairs of functional groups.
   - usually a ring forming reaction in the retrosynthetic direction to give you one FG rather than two.

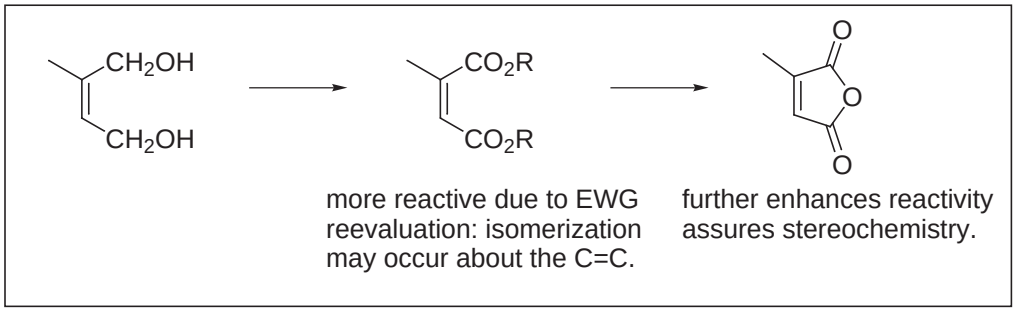


3. Functional group addition (FGA)
   - hard to recognize while working in the reverse direction.
   - introduce a double bond which then may key the recognition of a Diels-Alder reaction.



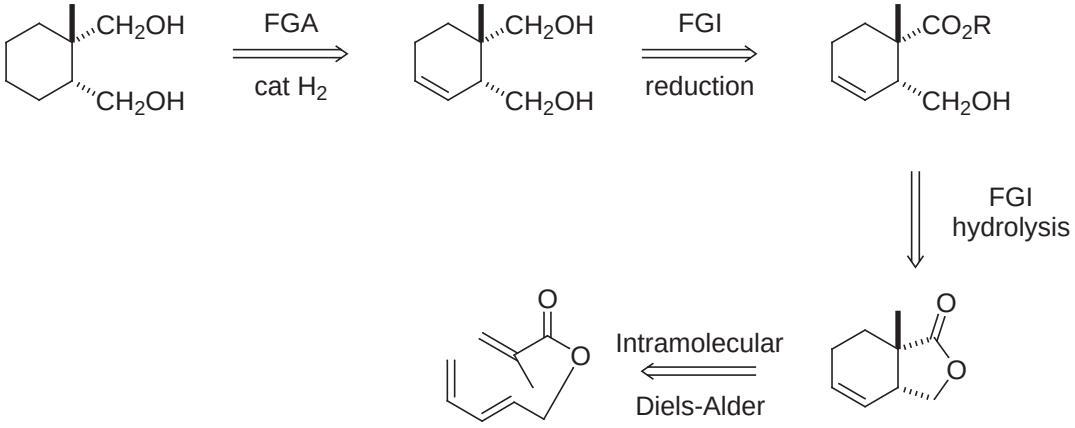
i.e., Diels-Alder reaction





But:

There is an alternative and still better Diels-Alder pathway that most would miss without careful consideration.



5. Evaluation of Pathways and Assignment of Merit
   a. excellent knowledge of organic chemistry
   b. suspect reactions must be recognized - only one poor step can ruin the synthesis
   c. control of stereochemistry is clear
   d. want opportunity for alternatives - reactions that look good on paper aren't always successful in lab

6. Selection of Specific Reactions and Reagents
   a. this also requires an excellent knowledge of organic chemistry
   b. check the literature for alternative reagents - it is wiser to change reagents than to change the entire synthesis if problems arise
   c. many reference texts are available

Larock	*Comprehensive Organic Transformations*
Fieser and Fieser	*Reagents for Organic Synthesis* Vol. 1-18
Paquette	*Encyclopedia of Reagents for Organic Synthesis*
Computer Databases	CLF, Reaccs, Scifinder, Beilstein, Isis

7. Selection of Reaction Conditions
   a. reaction temperature
   b. solvent
   c. knowledge of reaction mechanism
   d. consult current and background literature

8. Execution of the synthesis - most difficult and time consuming element of work
   a. easy: setting up and conducting the reaction
   b. difficult: interpreting the results from the reaction

C. Strategic Bond Analysis

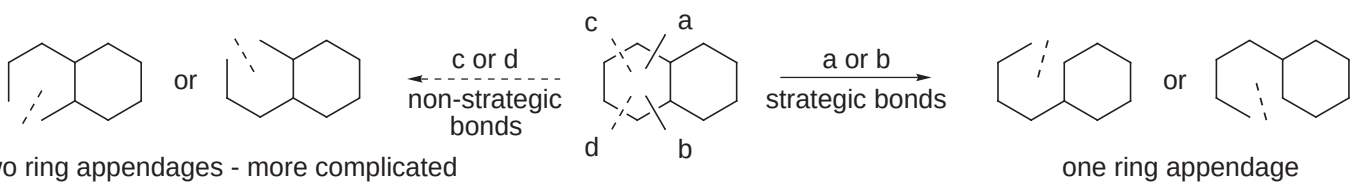
- For bridged ring systems Corey *J. Am. Chem. Soc.* **1975**, *97*, 6116.
- Most desirable bond disconnections in the antithetic direction minimize:

1. appendages
2. appendage chiral centers
3. medium or large size rings
4. bridged rings

Rule 1: Because it is easy to form common size rings, a strategic bond must be in a 4-7 membered primary ring. A primary ring is one which cannot be expressed as an envelope or two or more smaller rings. This is restricted to primary rings because ring forming reactions are strongly affected by the size of the smallest ring containing the newly forming bond.

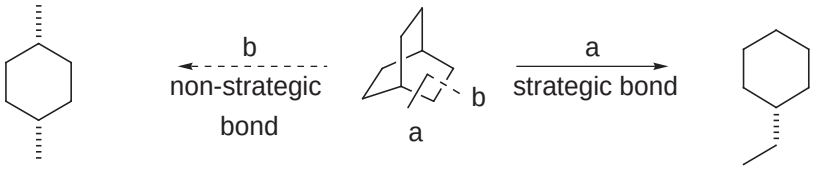
The six membered ring is not primary because it contains two smaller rings.

Rule 2a: A strategic bond must be directly attached to another ring (i.e. exo to another ring). This is because a ring disconnection which produces two functionalized appendages is harder to utilize than one which produces one or no functionalized appendages.

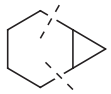


two ring appendages - more complicated

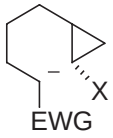
one ring appendage



Rule 2b: A strategic bond may not be exo to a preexisting 3-membered ring.

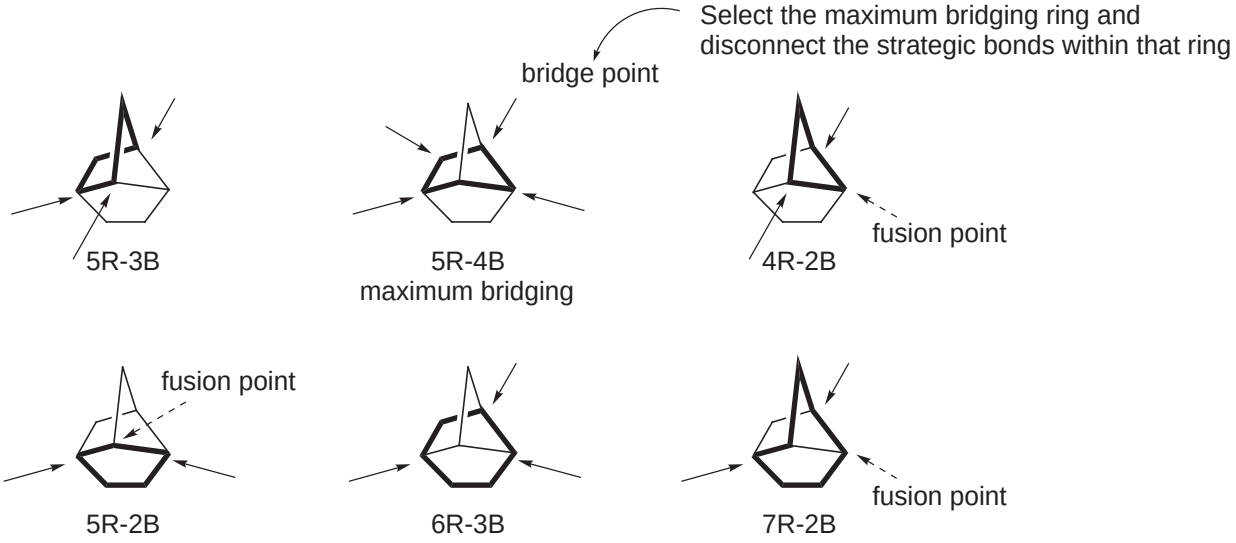


non-strategic even though exo to a ring

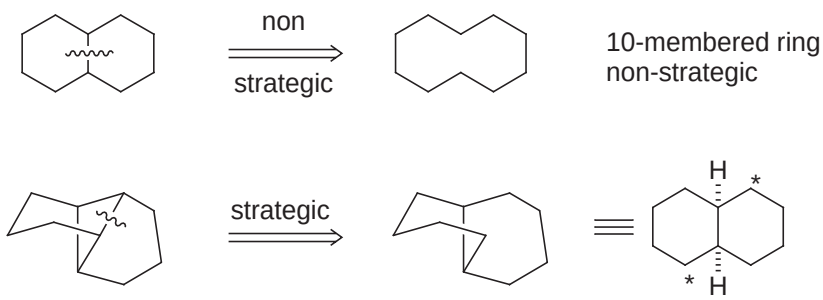


anion displacement reactions don't work well on a three membered ring

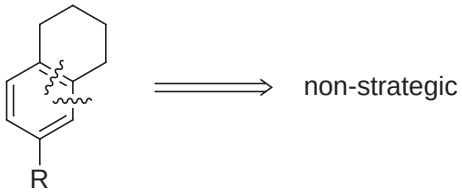
Rule 3: Strategic bonds should be in ring(s) which exhibit the greatest degree of bridging. The maximum bridging ring is selected from the set of synthetically significant rings which is defined as the set of all primary rings plus all secondary rings which are less than 8-membered. The maximum ring is that which is bridged, not fused at the greatest number of sites.



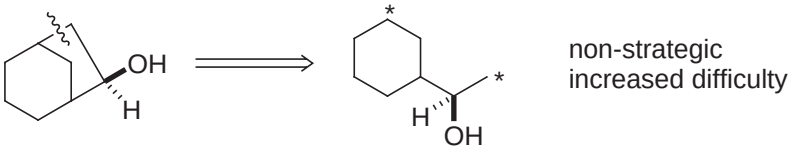
Rule 4: To avoid formation of >7-membered rings during the antithetic bond cleavage, any bond common to a pair of rings whose envelope is >7 is not strategic.



Rule 5: Bonds within aryl rings cannot be strategic.

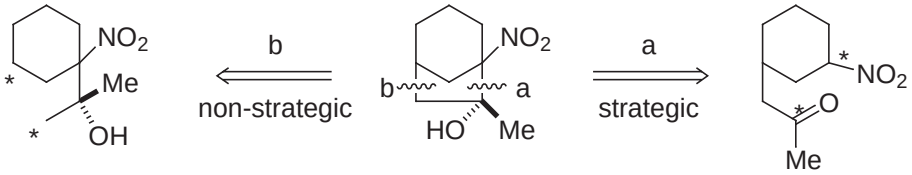


Rule 6a: If a disconnection leaves chiral atoms on the remaining arc then the disconnections cannot be strategic.



The stereochemistry is much harder to control
on the acyclic precursor than on the cyclic precursor

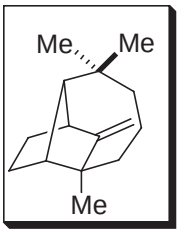
Rule 6b: Chiral atoms may be allowed if they appear directly at the point of attachment.



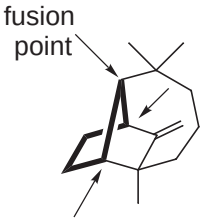
Rule 7: C-X Bonds (X = heteroatom) in rings will be strategic.

C-X bonds are easier to form than C-C

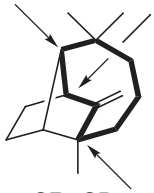
D. Total Synthesis Exemplified with Longifolene



1. Strategic Bond and Retrosynthetic Analysis



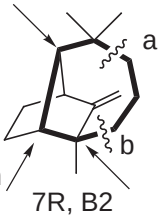
5R, B2



8R, 3B

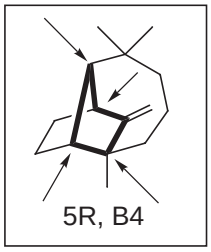
not a fusion point even though it is in a 1,2 relationship

8 ring - secondary

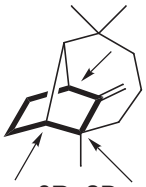


7R, B2

- Ho disconnection (a)
- Kuo disconnection (b)

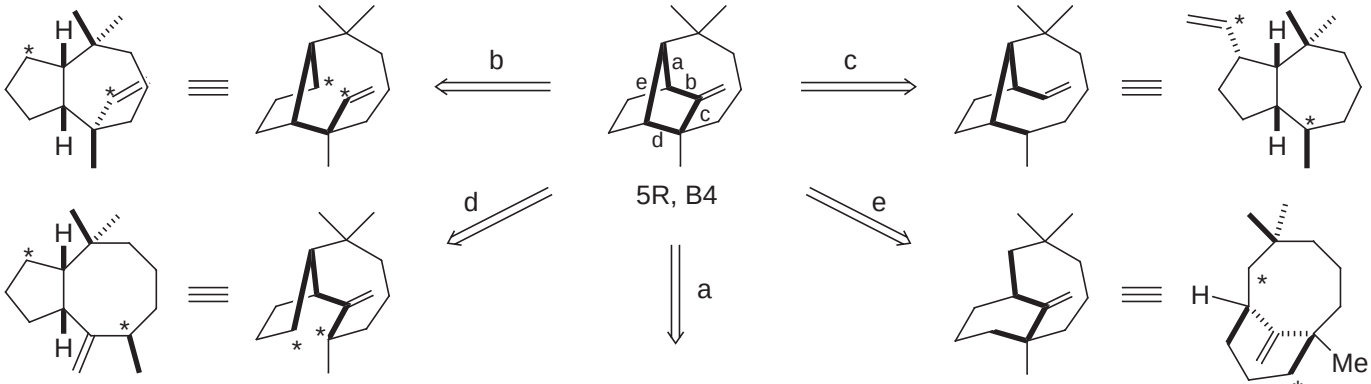


5R, B4



6R, 3B

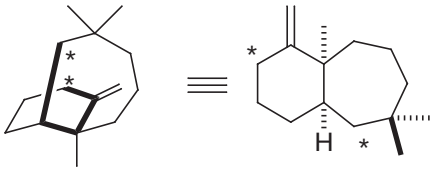
Fusion vs. bridge points: there must be at least one carbon (not in the ring in question) between the carbon in question and another carbon in the ring for it to be a bridgepoint.



non-strategic gives 8-membered ring

- Oppolzer but via 5-membered ring

non-strategic gives 8-membered ring

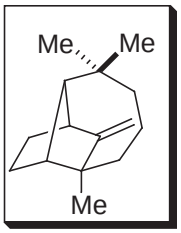


much simpler than longifolene!

- Corey and McMurry disconnection
- Schultz disconnection

- Simultaneous or sequential b/d bond disconnection: Brieger, Fallis (Diels-Alder), Johnson (cation-olefin).
- Simultaneous a/e bond disconnection: Schultz (indirect via vinylcyclopropane rearrangement).

2. Corey Synthesis: *J. Am. Chem. Soc.* **1961**, *83*, 1251; **1964**, *86*, 478.



Intramolecular Michael Addition (Santonin-Santonic Acid)
Robinson Annulation
Wittig Reaction
Pinacol Ring Expansion
Dithiane Reduction
Chromatographic Resolution through Diastereomeric Derivatization (Product)

3. McMurry Synthesis: *J. Am. Chem. Soc.* **1972**, *94*, 7132.

Intramolecular Enolate-Epoxide Addition (Alkylation)
Dibromocarbene Addition, Ring Expansion
Ethyl Diazoacetate Ring Expansion
Organocuprate 1,4-Additions
Intramolecular Aldol Reaction, Transannular Reactions
Fragmentation Reaction

4. Brieger Synthesis: (attempted) *J. Am. Chem. Soc.* **1963**, *85*, 3783.

Diels-Alder Reaction
Intramolecular Diels-Alder Reaction
1,5-Hydrogen Migration of Cyclopentadienes

5. Johnson Synthesis: *J. Am. Chem. Soc.* **1975**, *97*, 4777.

Organocuprate 1,4-Addition, Regiospecific Enolate Trap
Cation-Olefin Cyclization

6. Oppolzer Synthesis: *J. Am. Chem. Soc.* **1978**, *100*, 2583.
Helv. Chim. Acta **1984**, *67*, 1154.

Enamine Acylation
Photochemical [2 + 2] Cycloaddition
Retro-Aldol Fragmentation Reaction
Wittig Reaction
Simmons-Smith Cyclopropanation
Hydrogenation of Cyclopropanes
Classical Resolution via Crystallization of Diastereomeric Salts

7. Schultz Synthesis: *J. Org. Chem.* **1985**, *50*, 916.

Birch Reductive Alkylation
Retro Cheletropic Cycloaddition
1,3-Dipolar Cycloaddition
Vinylcyclopropane Rearrangement
Asymmetric Synthesis via Substrate Chiral Auxiliary

8. Fallis Synthesis: *J. Am. Chem. Soc.* **1990**, *112*, 4609.
J. Org. Chem. **1993**, *58*, 2186.

Intramolecular Diels-Alder Reaction
Barton Free Radical Deoxygenation Reaction
Acetate Pyrolysis
Chromatographic Resolution through Diastereomeric Derivatization (Starting Material)

9. Kuo Synthesis: *Can J. Chem.* **1988**, *66*, 1794.

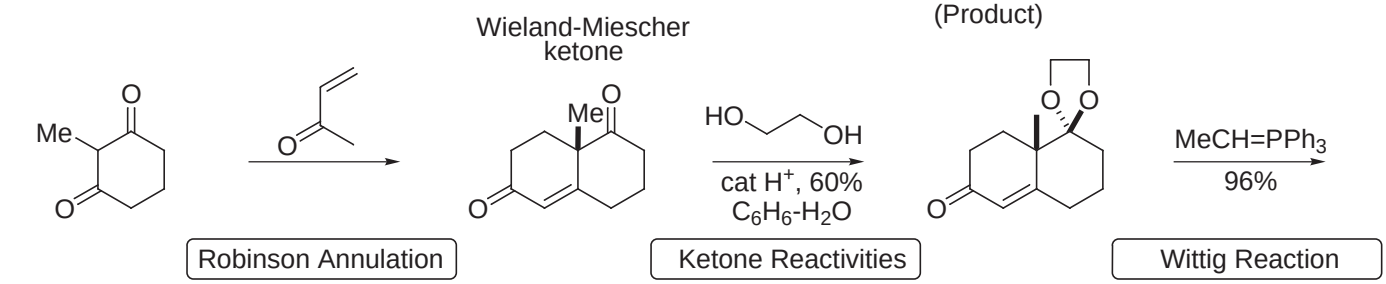
Intramolecular Aldol Addition
Wagner-Meerwein Rearrangement

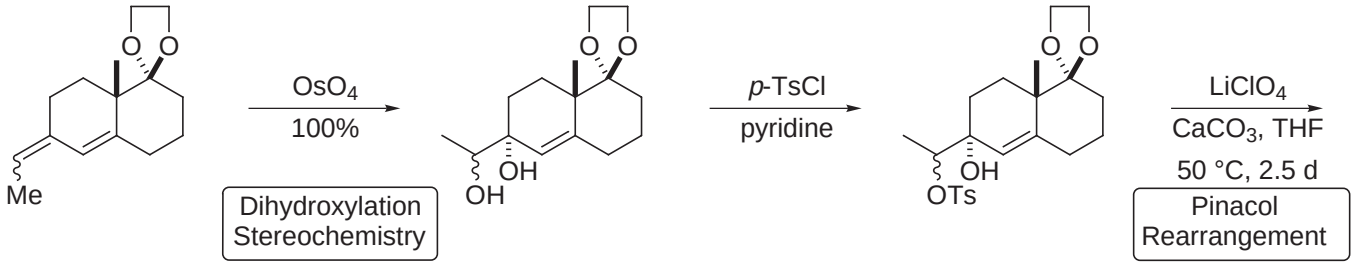
10. Ho Synthesis: *Can J. Chem.* **1992**, *70*, 1375.

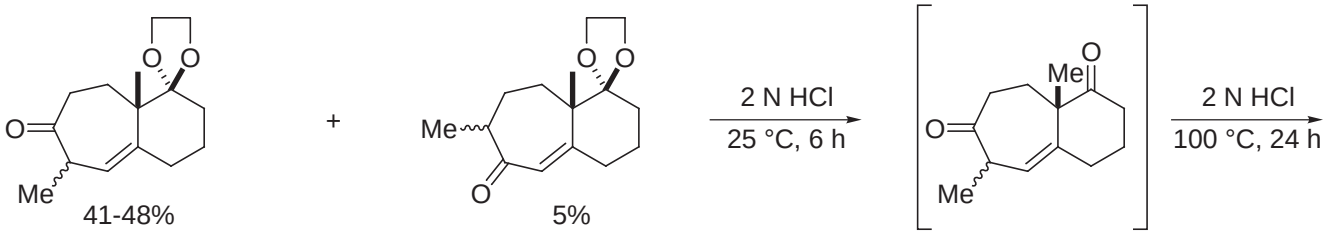
Ethyl Diazoacetate Ring Expansion
Alkylative Esterification

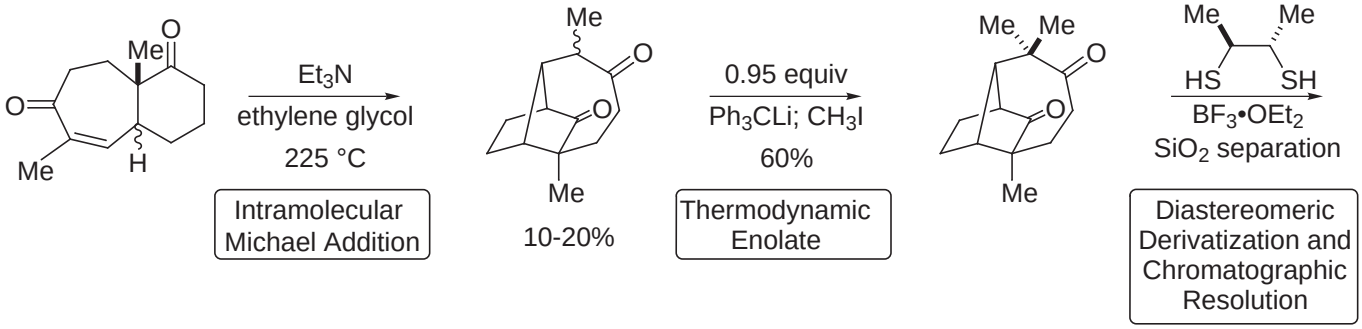
2. Corey Synthesis: *J. Am. Chem. Soc.* **1961**, *83*, 1251.
J. Am. Chem. Soc. **1964**, *86*, 478.

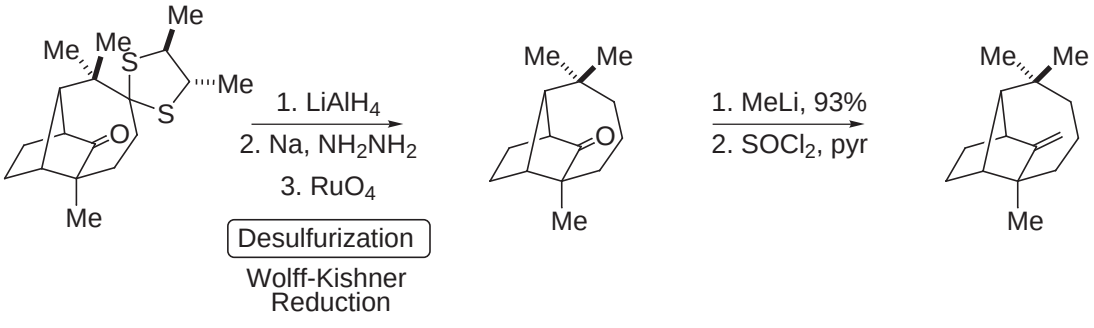
Intramolecular Michael Addition
Robinson Annulation
Wittig Reaction
Pinacol Ring Expansion
Dithiane Reduction
Chromatographic Resolution through Diastereomeric Derivatization (Product)

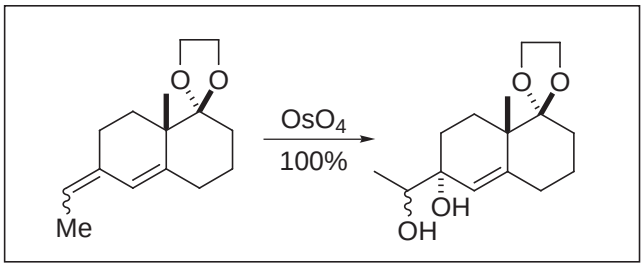




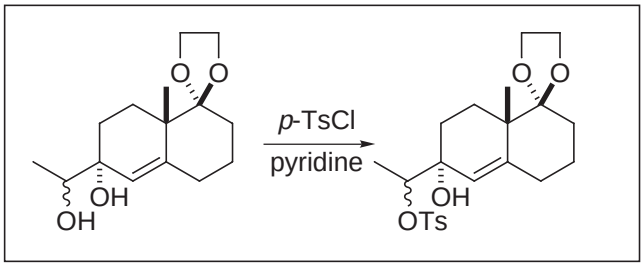




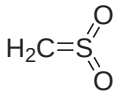




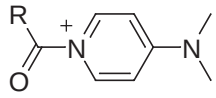
Osmylation
- large reagent reacts preferentially with more accessible double bond and from the least hindered face. Typically, this is from the equatorial direction but one 1,3-diaxial H is removed and axial approach now observed

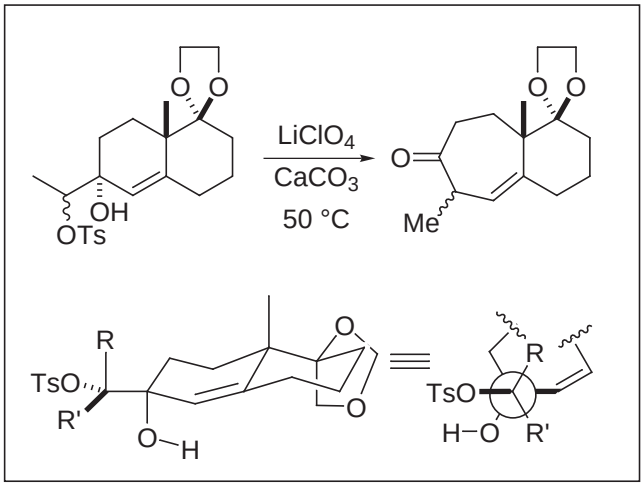


Selective Tosylation
- rates: 1° > 2° > 3°
- 3° alcohols react very slowly
- MsCl and Et_3N generates sulfene which will react with 1°, 2°, 3° OH to give the mesylate

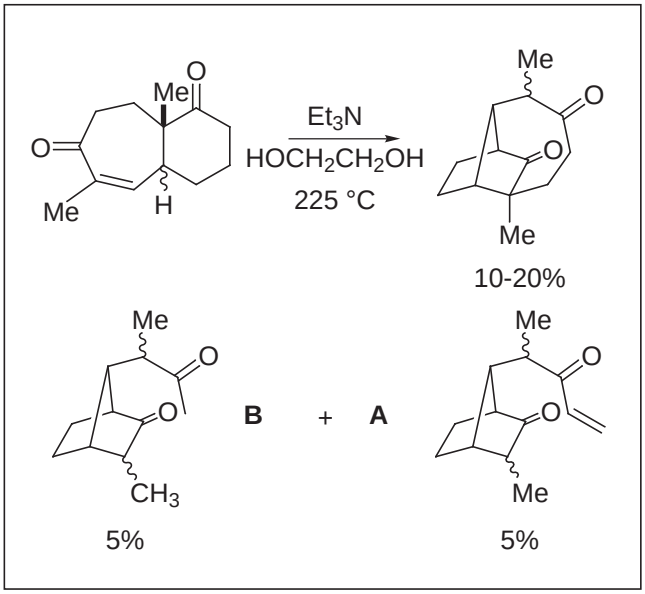


- Also note the use of DMAP to acylate 3° alcohols via

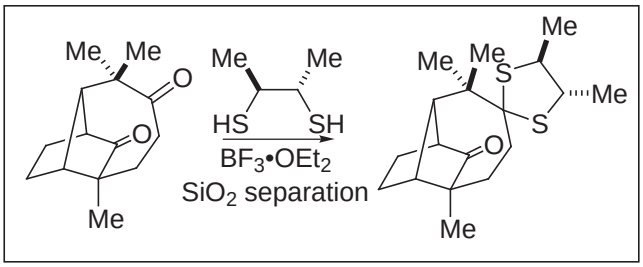




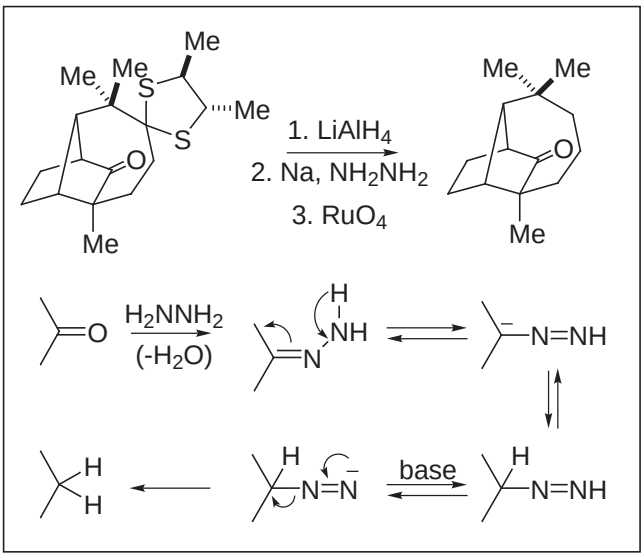
Pinacol Rearrangement
- $LiClO_4$ used for free Li^+ ion to accelerate solvolytic loss of TsO group
- migration of unsaturated alkyl group observed preferentially
- *trans* antiperiplanar arrangement



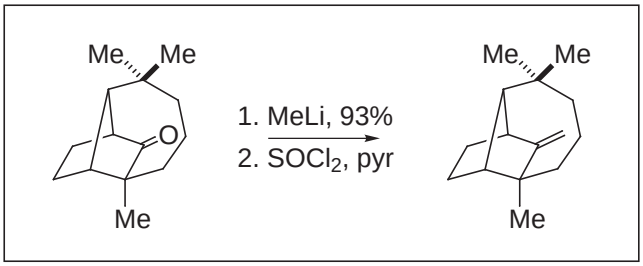
Intramolecular Michael Addition
- only *cis* product undergoes Michael
- side products include the retro-Michael product **A** and the OH^- addition and retro aldol product **B**



Thio-ketalization (Derivatization)
- other carbonyl much more hindered
- diastereomers arise that are separable by conventional chromatography



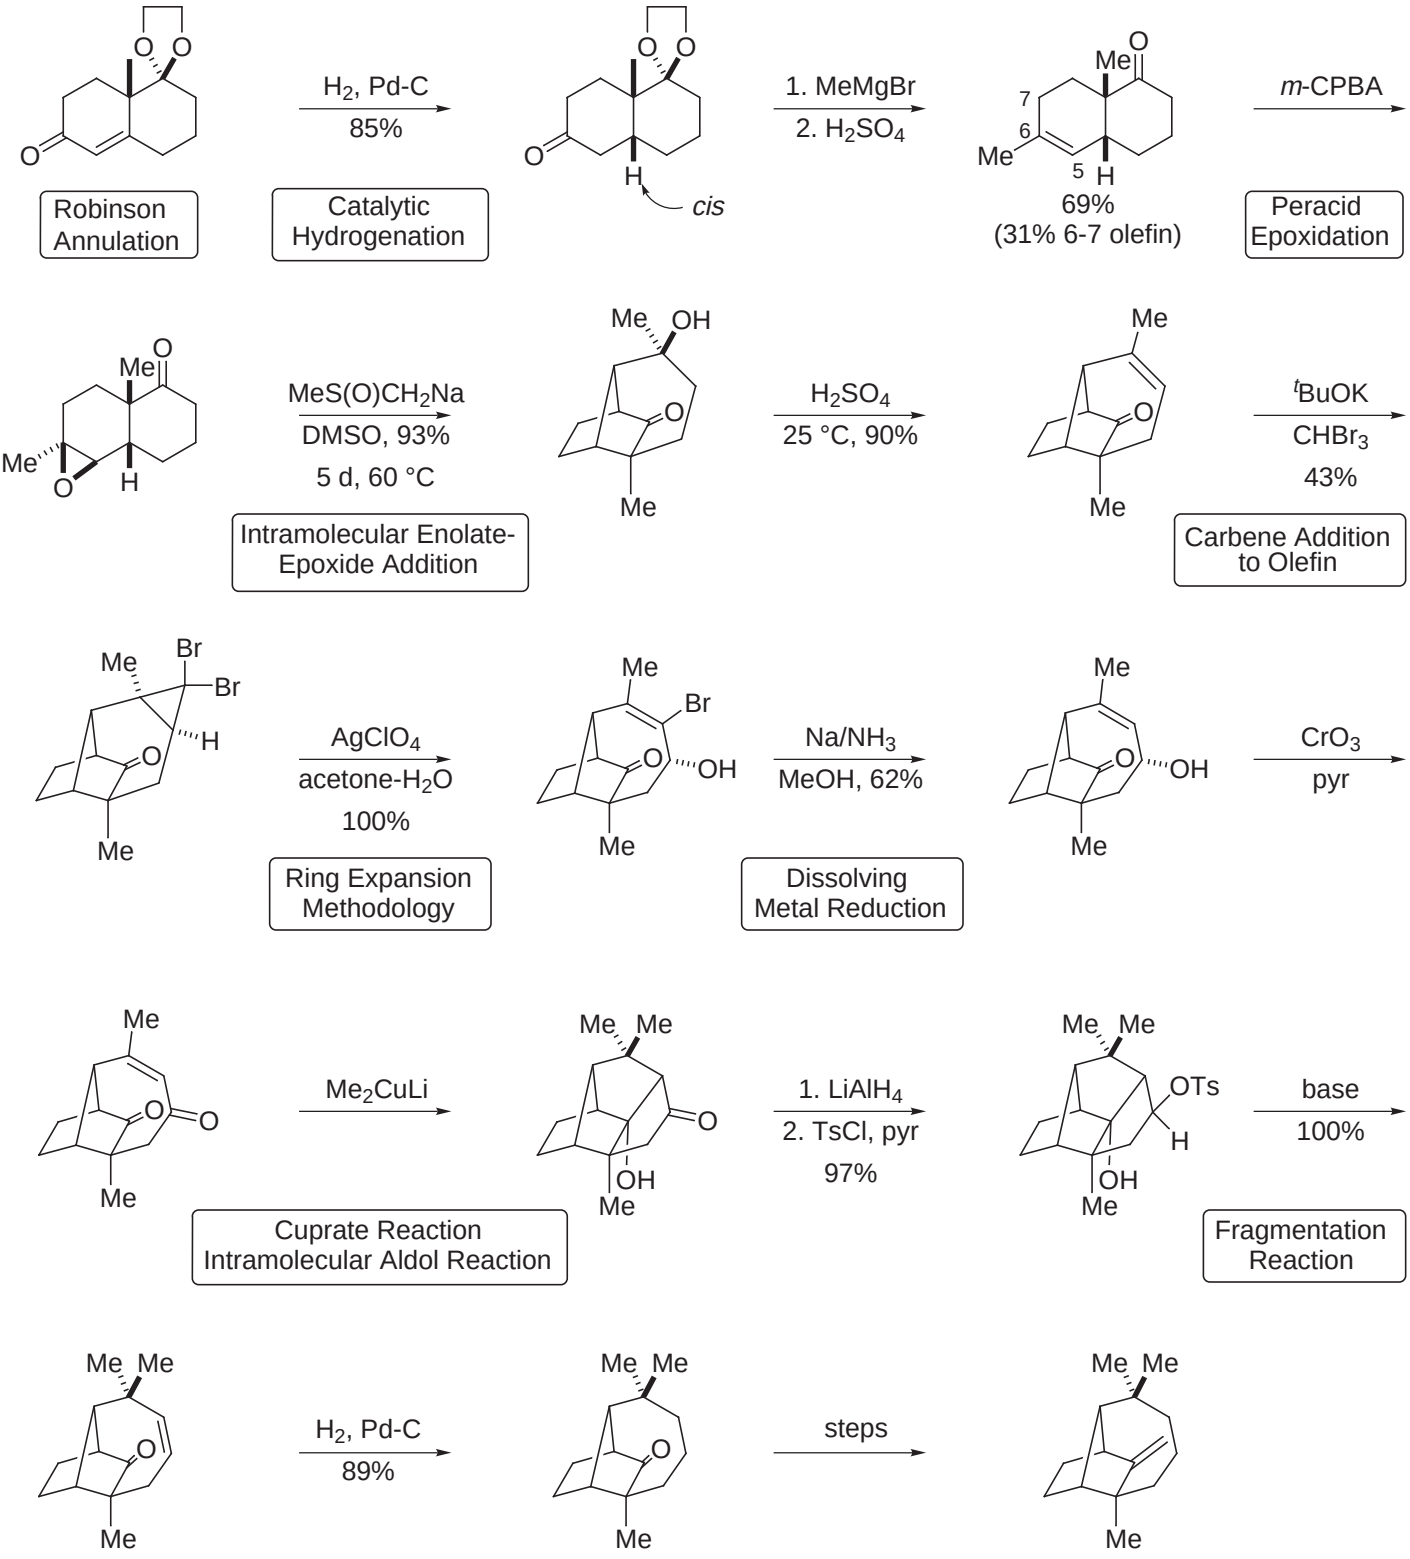
Desulfurization
- direct Wolff-Kishner failed
- $LiAlH_4$ protects ketone from reduction
- today: Ra-Ni better for desulfurization and would avoid need to protect ketone
- Wolff-Kishner reduction of dithiane

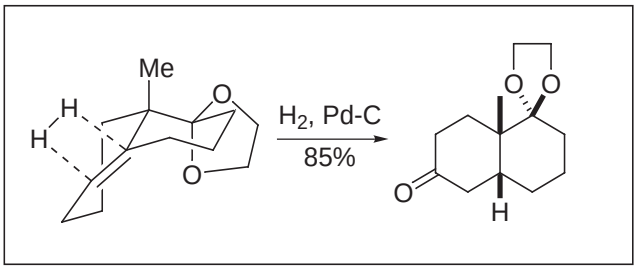


Olefination
- Wittig reaction unsuccessful, ketone too hindered
- two-step procedure adopted

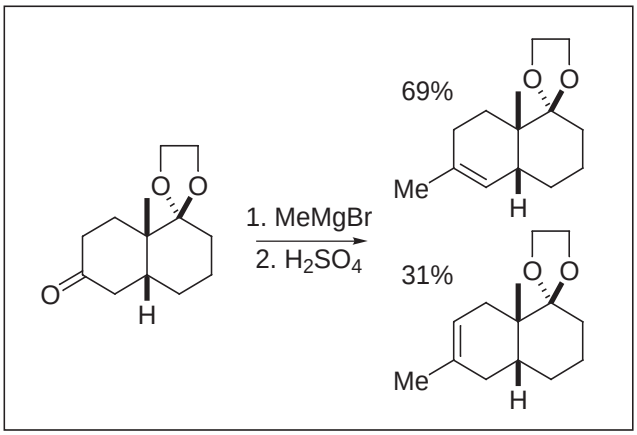
3. McMurry Synthesis: *J. Am. Chem. Soc.* **1972**, *94*, 7132.

Intramolecular Enolate-Epoxide Addition
Dibromocarbene Addition, Ring Expansion
Ethyl Diazoacetate Ring Expansion
Organocuprate 1,4-Additions
Intramolecular Aldol Reaction
Transannular Reactions
Fragmentation Reaction

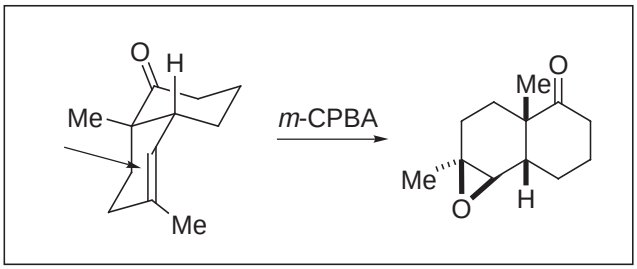




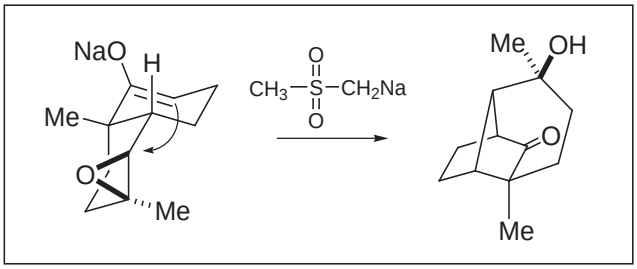
Hydrogenation
- known conditions to give *cis* stereochemistry
- H_2 comes in from less hindered face
- heteroatoms can also direct H_2 to their face



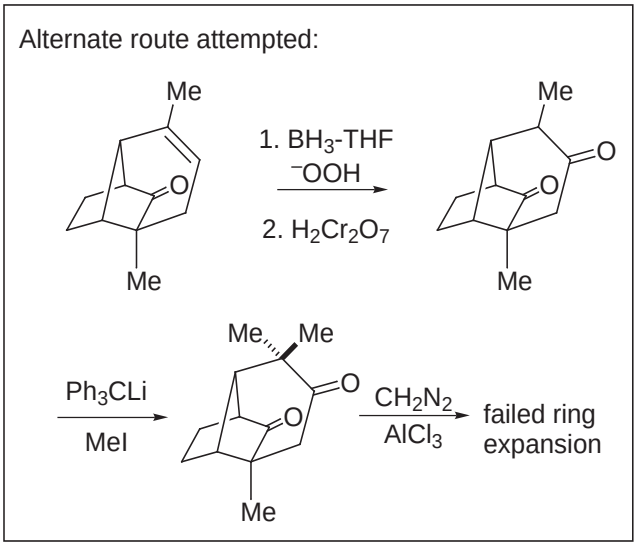
Acid-catalyzed Elimination
- *cis*-ring fusion prefers $\Delta^{2,3}$ double bond
- *trans*-ring fusion prefers $\Delta^{3,4}$ double bond
- known from steroid chemistry



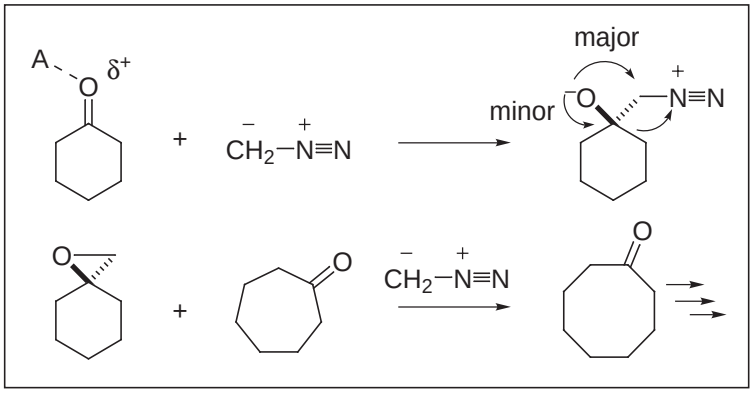
Epoxidation
- epoxidation from the least hindered face
- no competitive Baeyer-Villiger at ketone
- trisubstituted olefin more reactive than ketone



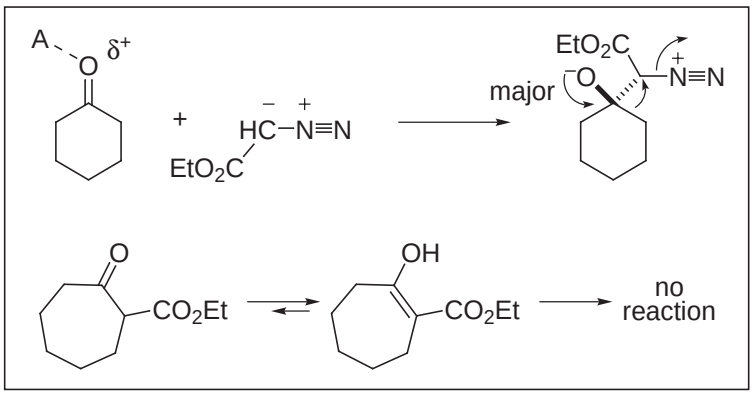
Intramolecular Epoxide Addition
- very slow epoxide opening due to steric encumbrance of Me group
- benefits from irreversible nature of epoxide opening



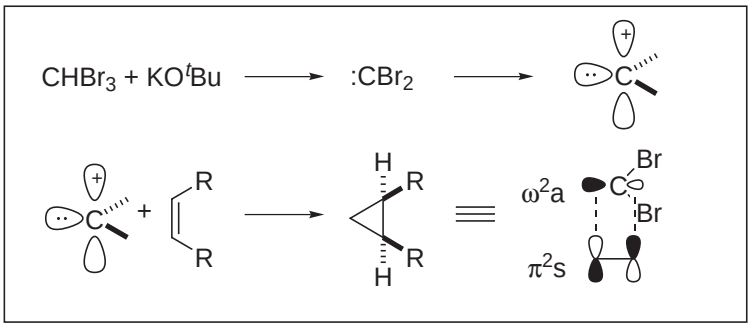
Alternate Route
- hydroboration-oxidation gave ketone
- methylation conditions specifically employed to avoid over-methylation
- ring expansion with CH_2N_2 did not proceed



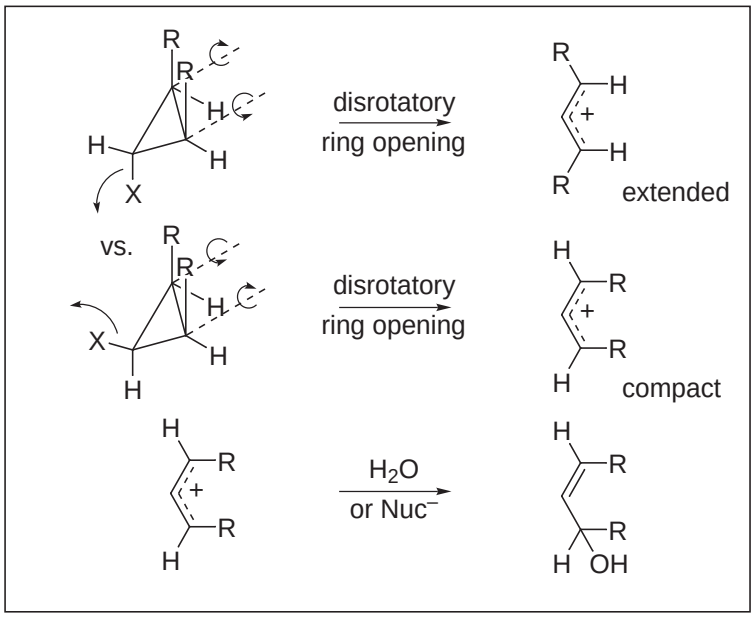
Diazomethane Ring Expansion
- CH_2N_2 poor nucleophile
- $AlCl_3$ added to activate carbonyl
- many side reactions possible
- CH_2N_2 explosive, difficult to use
- products equally reactive toward additional expansions/epoxidations



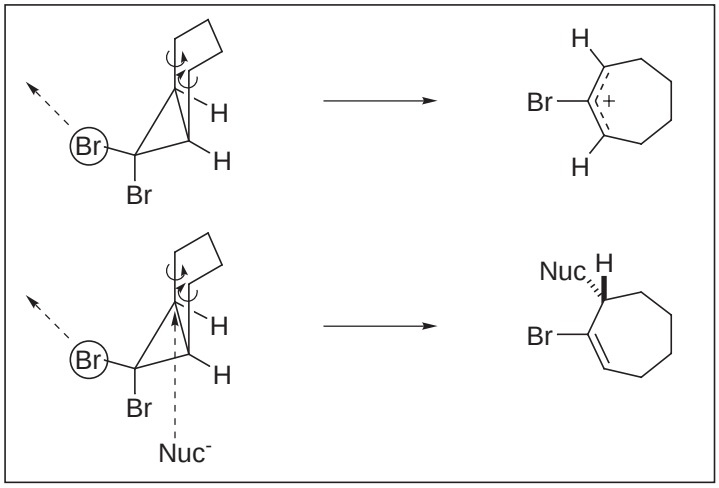
Diazoacetate Ring Expansion
- improvement over diazomethane
- product in enol form and will not further react with reagent
- reagent stable, transportable and readily available
- ultimately employed in the later Ho synthesis



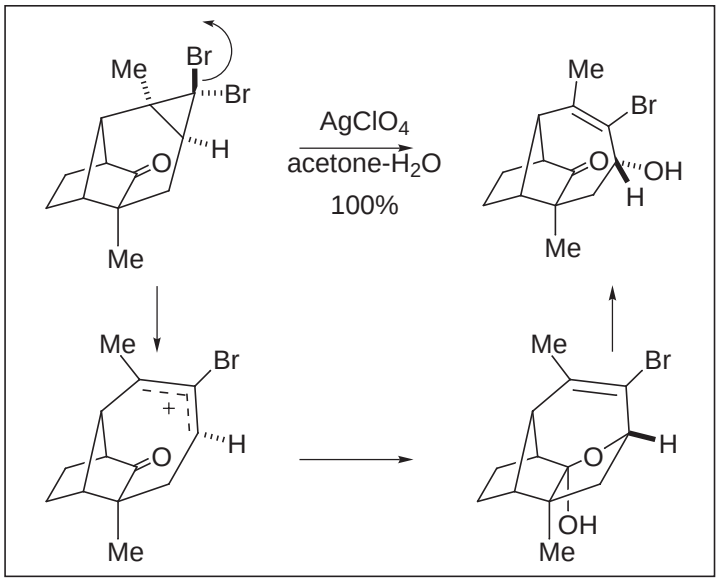
Carbene Addition and Ring Expansion
- singlet carbene has electrophilic character, and undergoes stereospecific reaction with olefins (no scrambling as observed with triplet carbene)
- Br can donate electrons into the empty p-orbital, thus stabilizing the singlet carbene
- cheletropic cycloaddition occurs with olefin geometry maintained via a $\pi^2s + \omega^2a$ cycloaddition



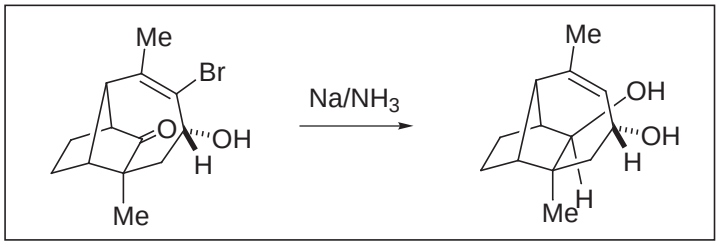
Disrotatory Ring Opening of Halocyclopropanes
- leaving group will influence direction of ring opening
- departure of LG simultaneous with disrotatory ring opening
- substituents *syn* to the departing group will move towards one another while they move away from each other if *anti* leaving group. Since this system is confined to a 7-membered ring, the R groups must move toward each other to give the compact alkyl cation and it is the *syn* bromide that is lost



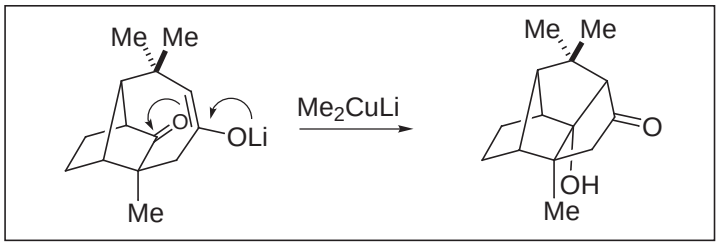
In Fused Bicyclic Systems
- imposed geometry of ring controls opening and directs leaving group
- nucleophile comes in *trans* to departing Br^-
- exception: bicyclo[5.1.0]octane can give the *trans* double bond via outward rotation
- *Chem. Commun.* **1967**, 294.
- *Chem. Commun.* **1968**, 1593.
- *J. Am. Chem. Soc.* **1970**, *92*, 2566.



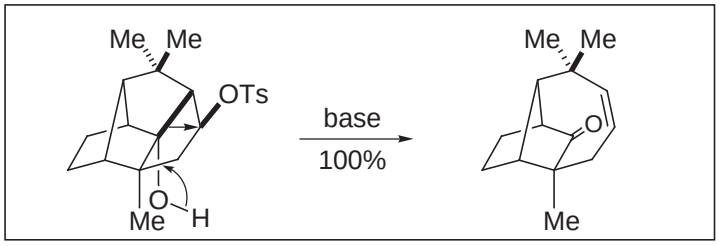
McMurry Application
- ring controls geometry of ring opening, thus only one bromine departs
- nucleophile (OH_2) enters *trans* to leaving Br
- no trap at other end of allyl cation - possible assistance of C=O



Dissolving Metal Reduction
- stereochemistry of reduced OH - most stable product
- reduction of the vinyl halide



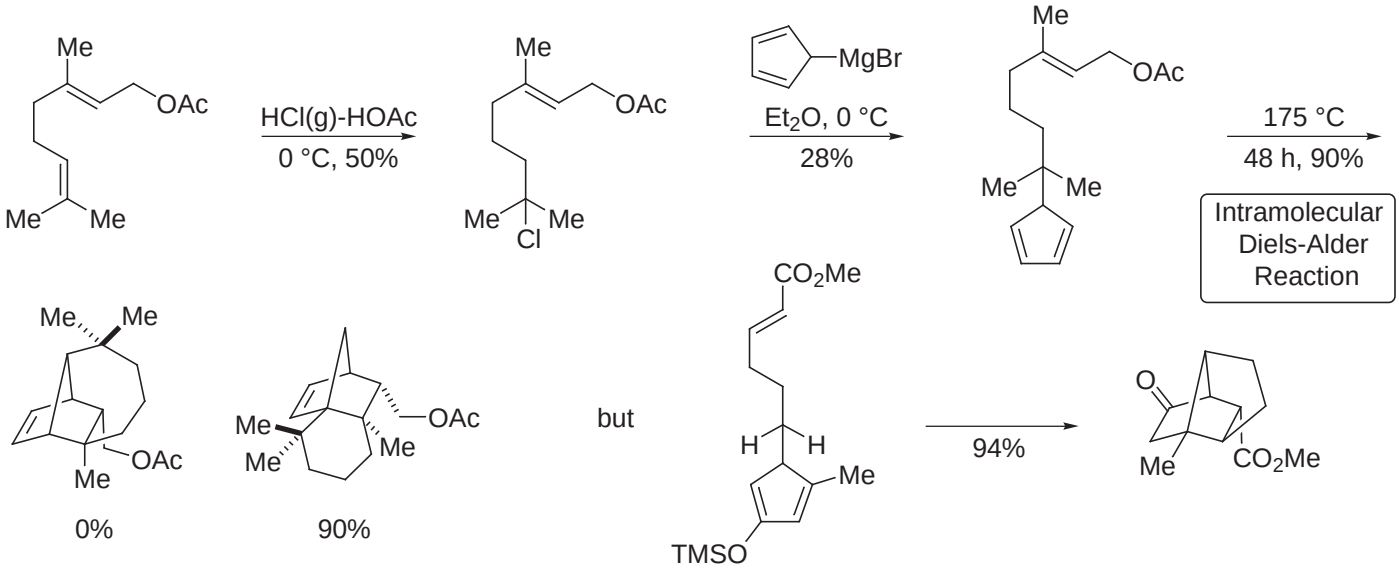
Cuprate Addition - Intramolecular Aldol Reaction
- cuprate adds in Michael fashion to generate enolate
- enolate then attacks carbonyl in intramolecular fashion



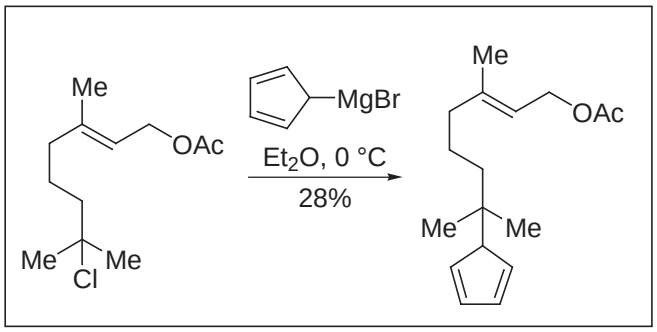
Fragmentation
- reduction occurs from least hindered face
- tosylation selective for 2° > 3°

4. Brieger Synthesis: (attempted) *J. Am. Chem. Soc.* **1963**, *85*, 3783.

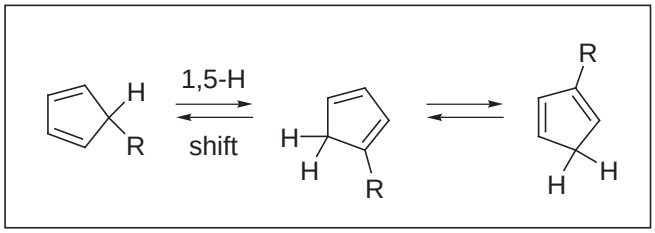
Diels-Alder Reaction
Intramolecular Diels-Alder Reaction
1,5-Hydrogen Migration of Cyclopentadienes



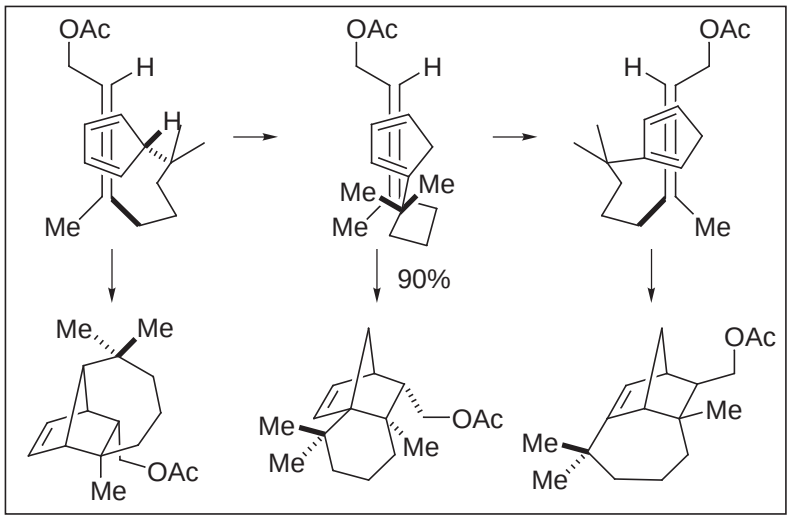
Snowden *Tetrahedron Lett.* **1981**, *22*, 98 and 101.



Grignard Addition
- alkylation at 3° center!
- nonbasic reagent, E2/E1 elimination not observed



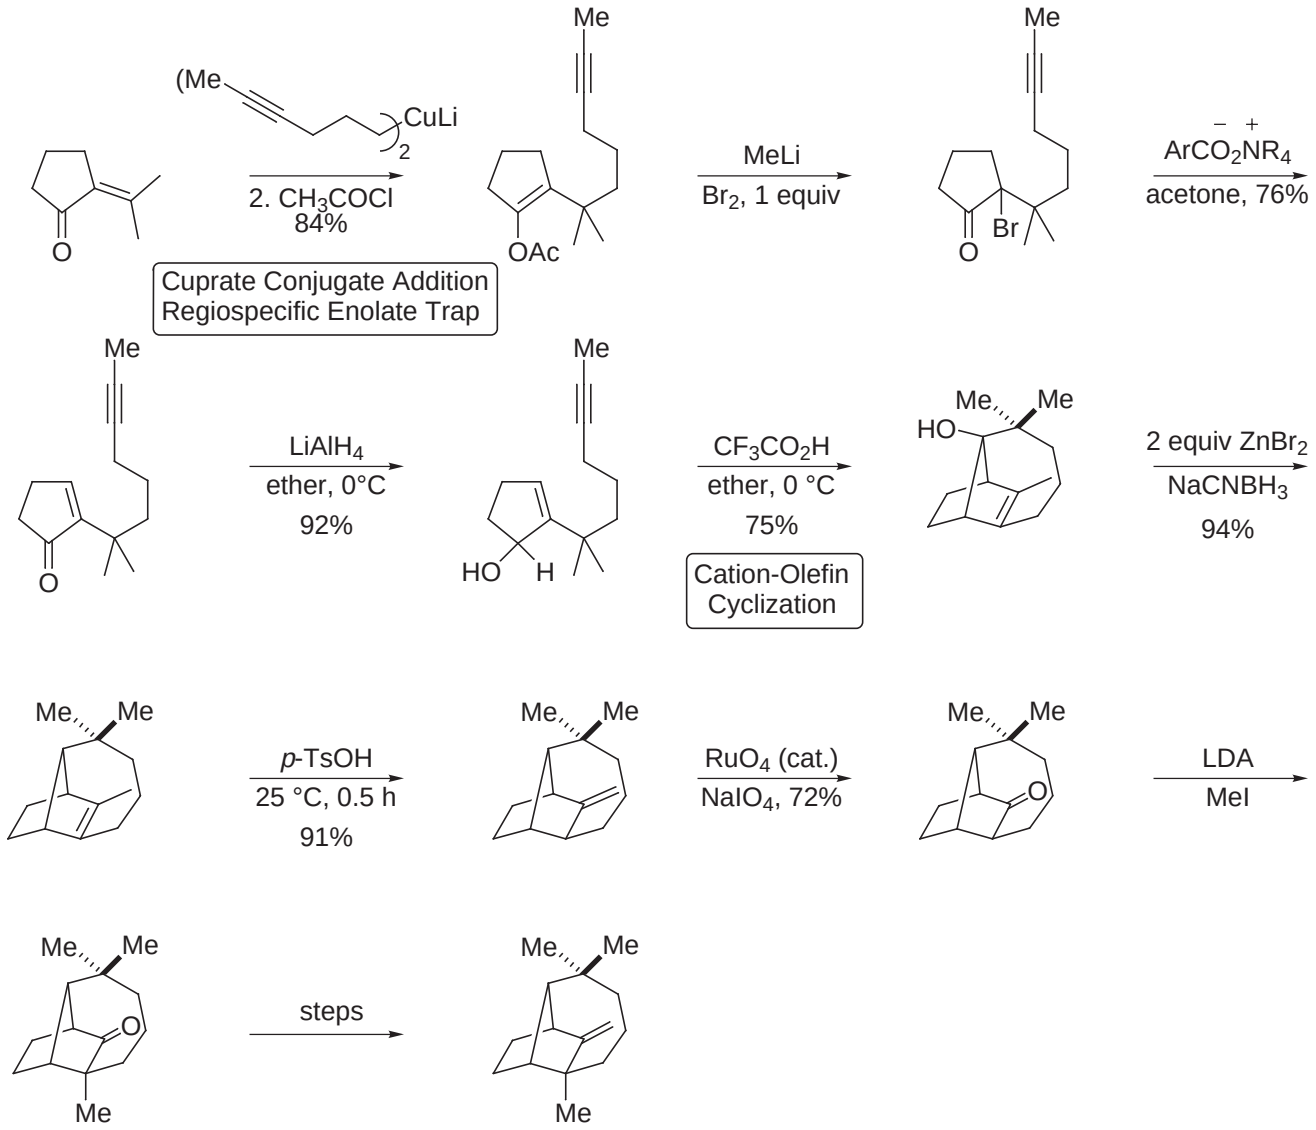
1,5 H-Shift
- proceeds at 0 °C
- causes failure of desired [4 + 2] cycloaddition for longifolene above

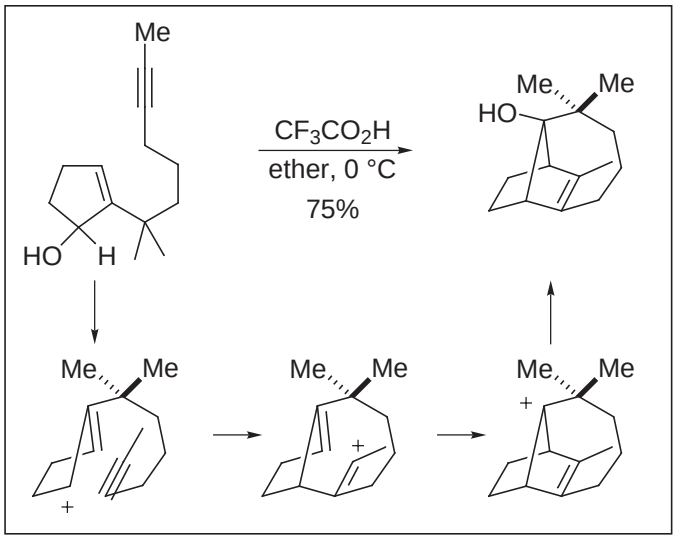


Intramolecular Diels-Alder
- at 175 °C, all three 1,5-H shift products present
- provide three different possible products
- only one product observed

5. Johnson Synthesis: *J. Am. Chem. Soc.* **1975**, *97*, 4777.

Organocuprate 1,4-Addition
Regiospecific Enolate Trap
Cation-Olefin Cyclization



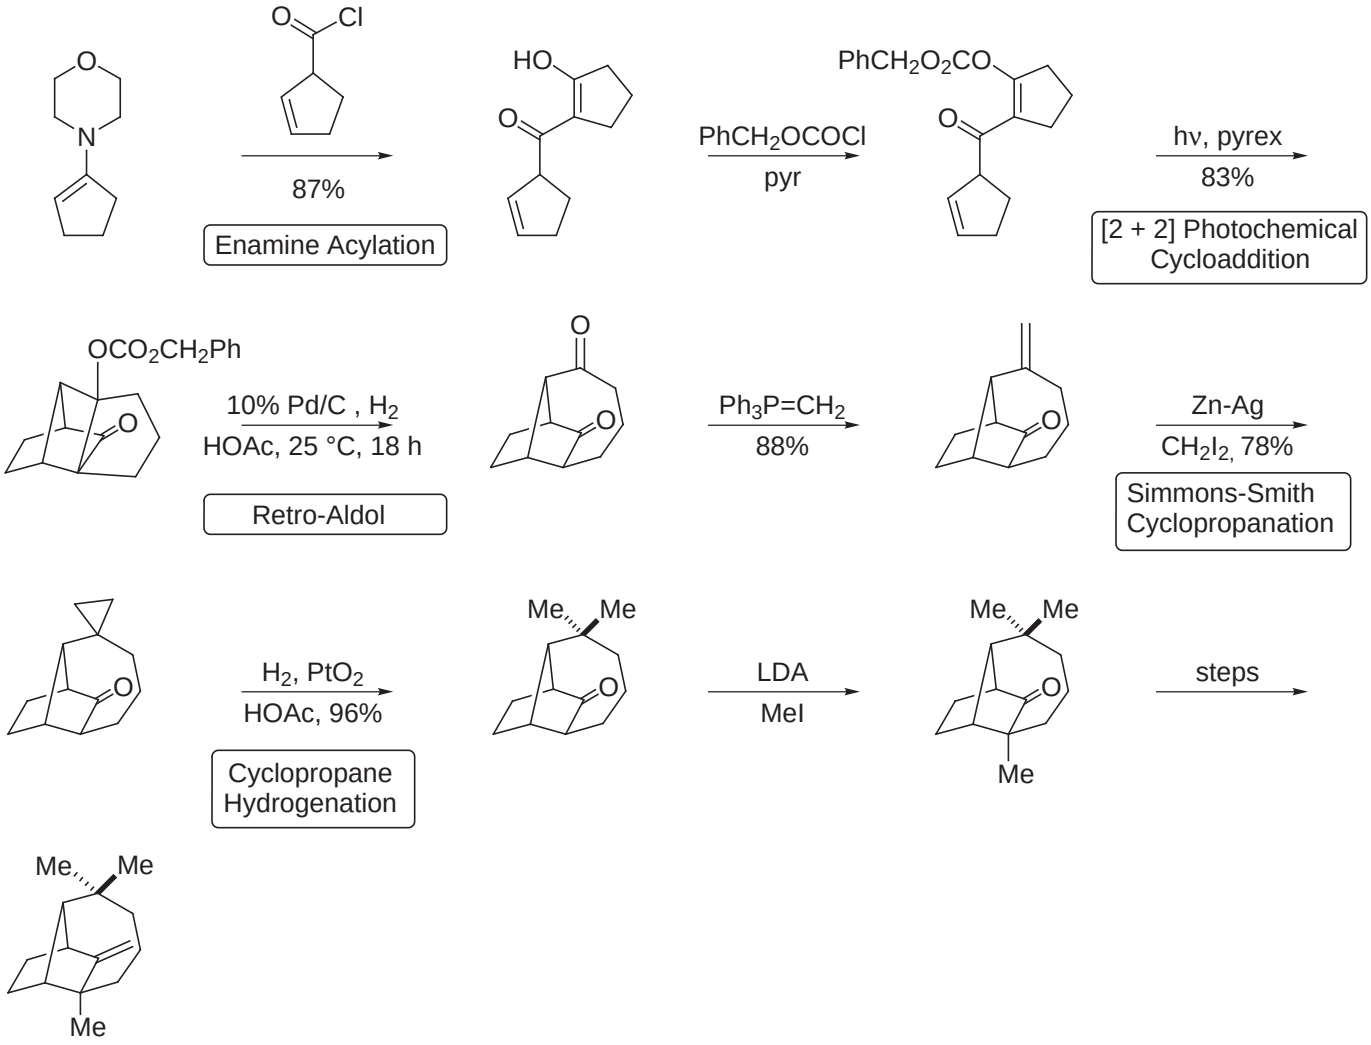


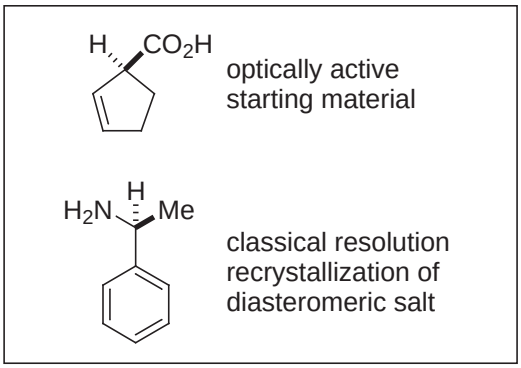
Cation-Olefin Cyclization
- 2° allylic alcohol for initiation site

6. Oppolzer Synthesis:

J. Am. Chem. Soc. **1978**, *100*, 2583.
Helv. Chim. Acta **1984**, *67*, 1154.

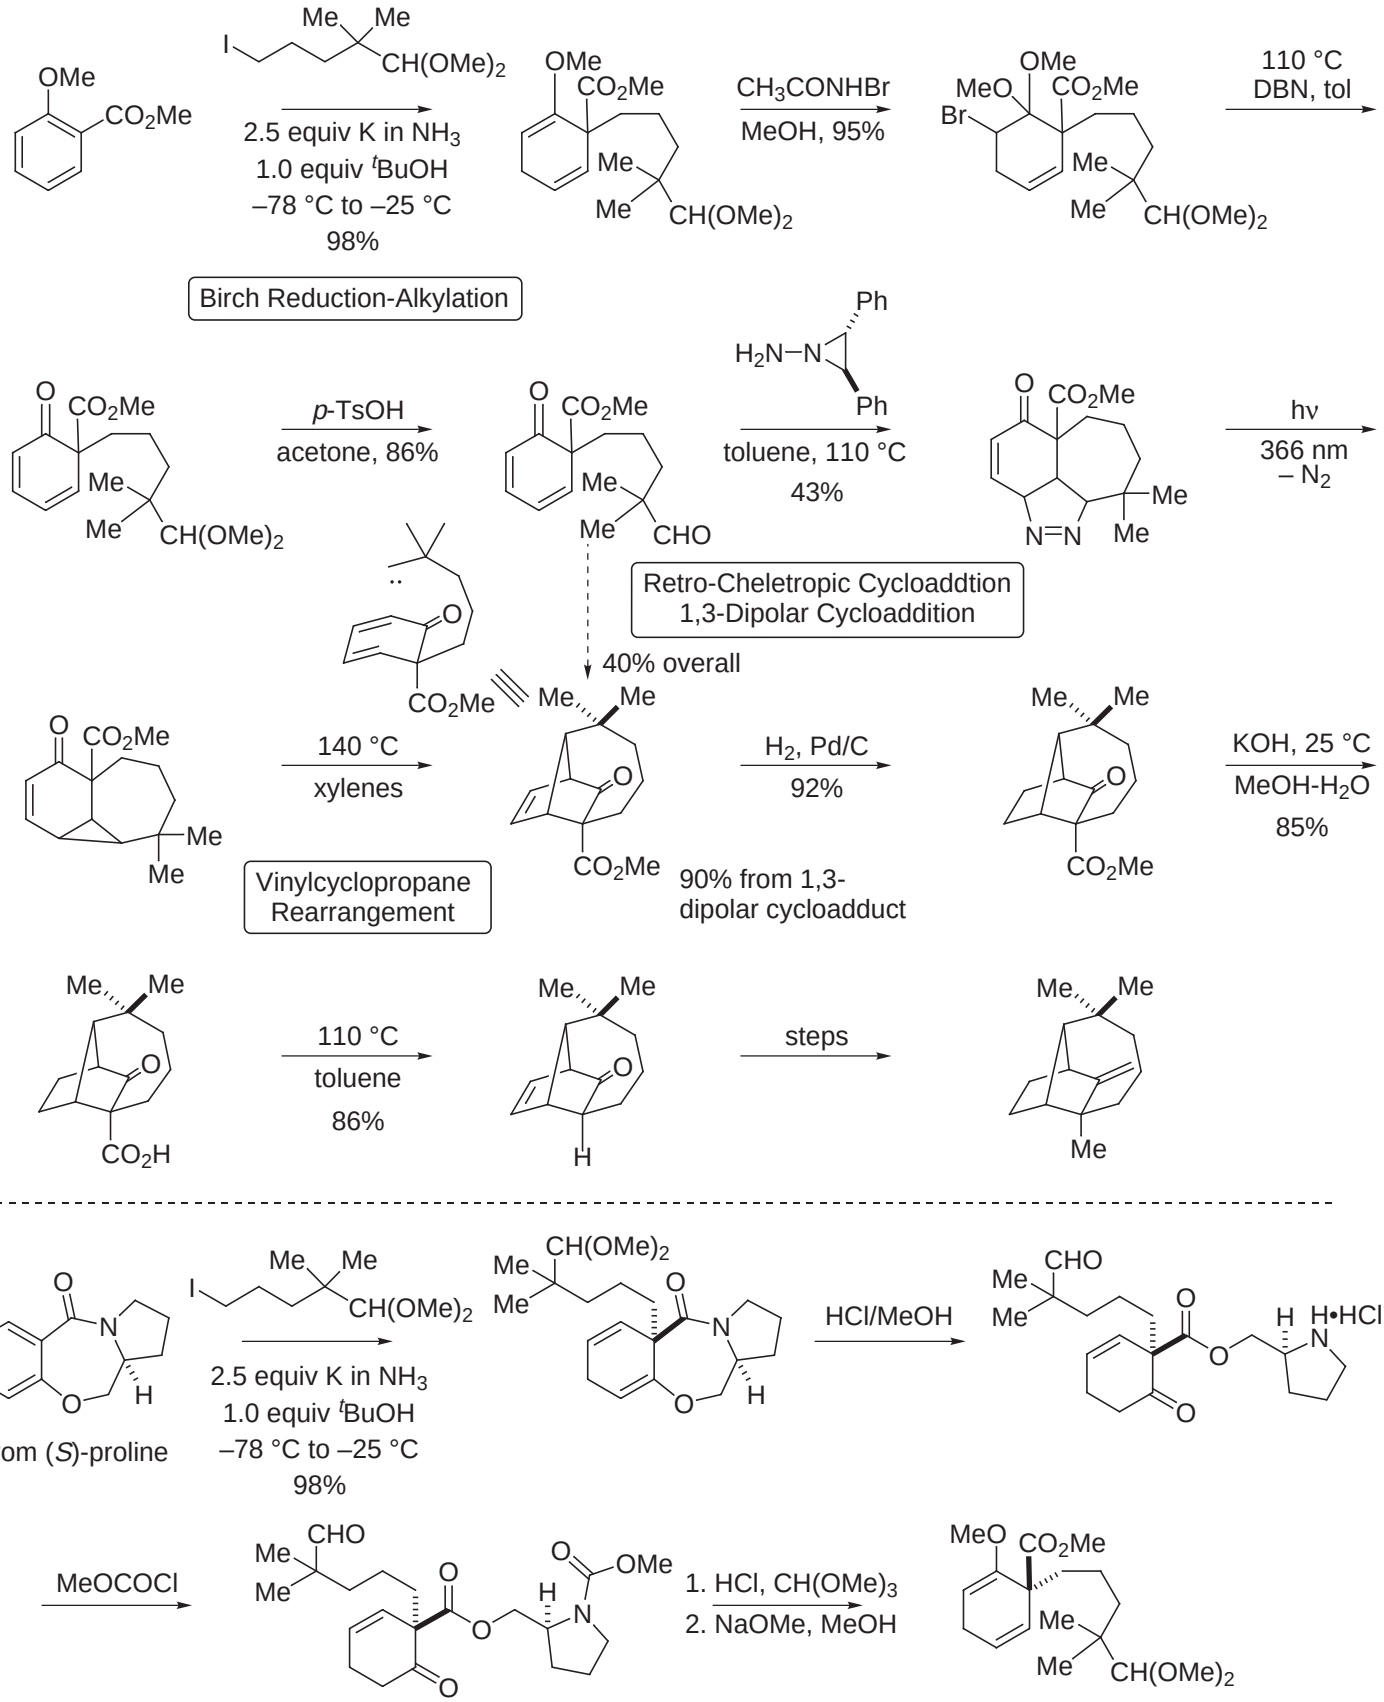
Enamine Acylation
Photochemical [2 + 2] Cycloaddition
Retro-Aldol Reaction
Wittig Reaction
Simmons-Smith Cyclopropanation
Hydrogenation of Cyclopropanes
Classical Resolution via Crystallization of Diastereomeric Salts

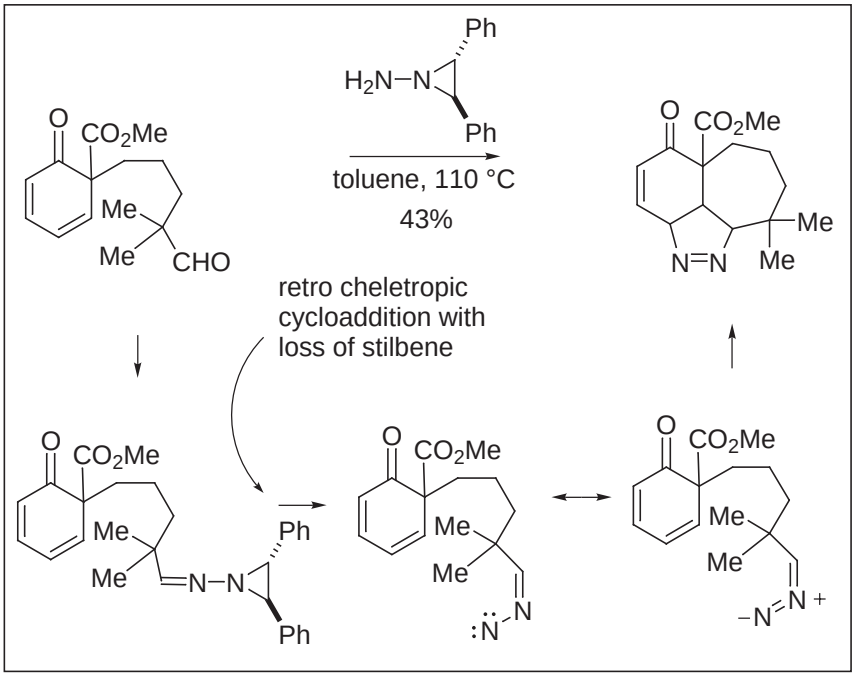




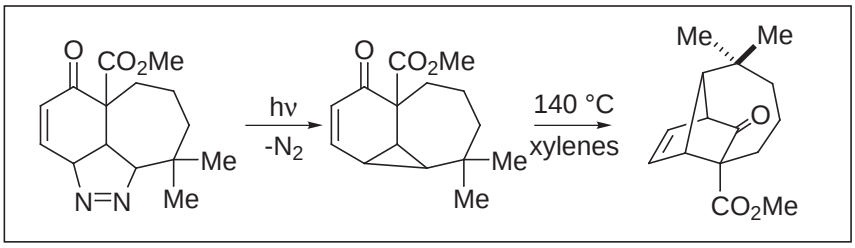
7. Schultz Synthesis: *J. Org. Chem.* **1985**, *50*, 916.

Birch Reductive Alkylation
Retro Cheletropic Cycloaddition
1,3-Dipolar Cycloaddition
Vinylcyclopropane Rearrangement
Asymmetric Synthesis
via Substrate Chiral Auxiliary

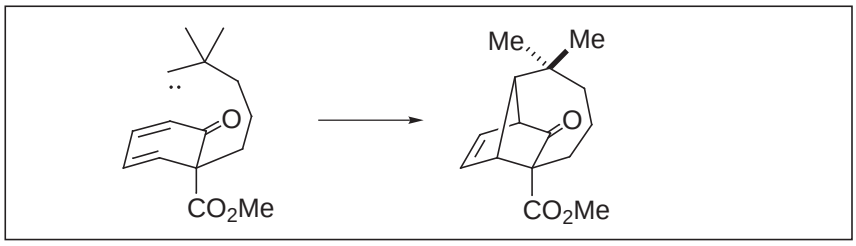




Retro Cheletropic Cycloaddition
and Subsequent 1,3-Dipolar Cycloaddition



Vinylcyclopropane Rearrangement
- 1,3-sigmatropic rearrangement

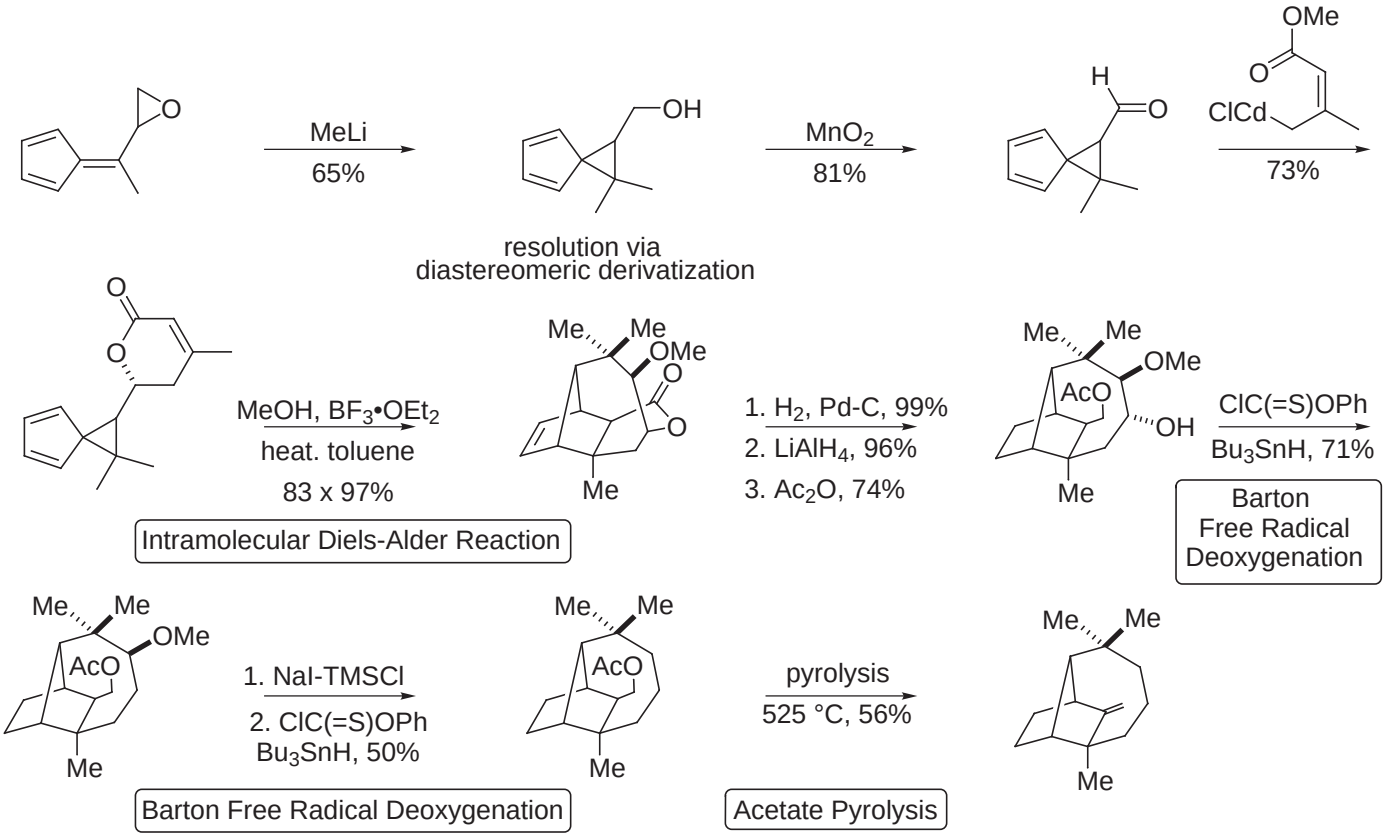


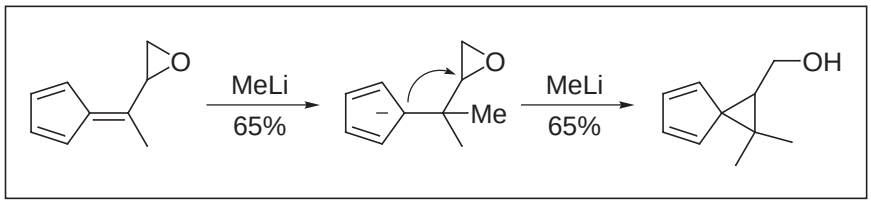
- This sequence is equivalent to adding the elements of a carbene 1,4 across a diene
- Is this $4e^- + 2e^-$ cycloaddition possible? Consider the Woodward-Hoffmann rules.

8. Fallis Synthesis:

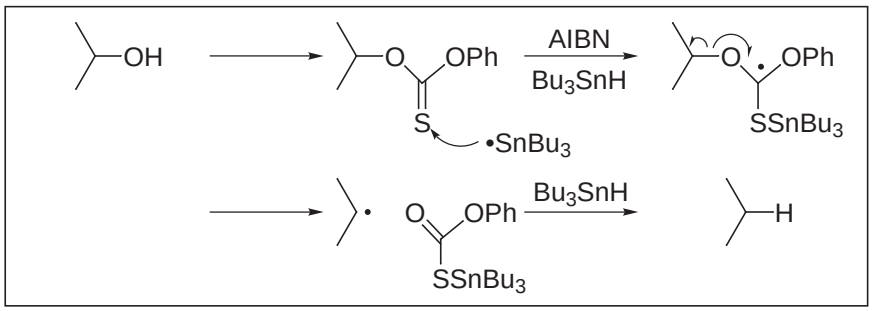
J. Am. Chem. Soc. **1990**, *112*, 4609.
J. Org. Chem. **1993**, *58*, 2186.

Intramolecular Diels-Alder Reaction
Barton Free Radical Deoxygenation Reaction
Acetate Pyrolysis
Chromatographic Resolution through Diastereomeric Derivatization (Starting Material)

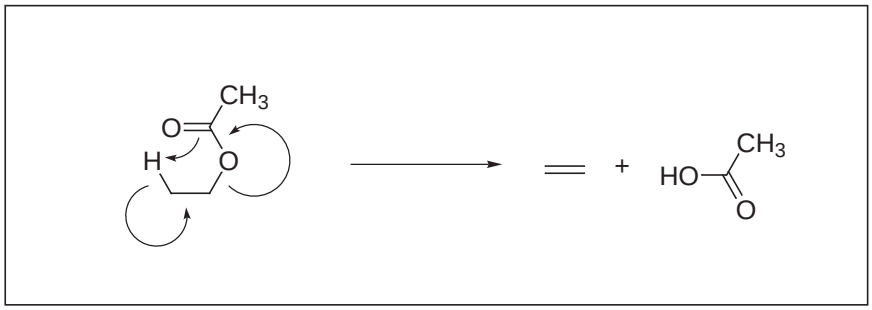




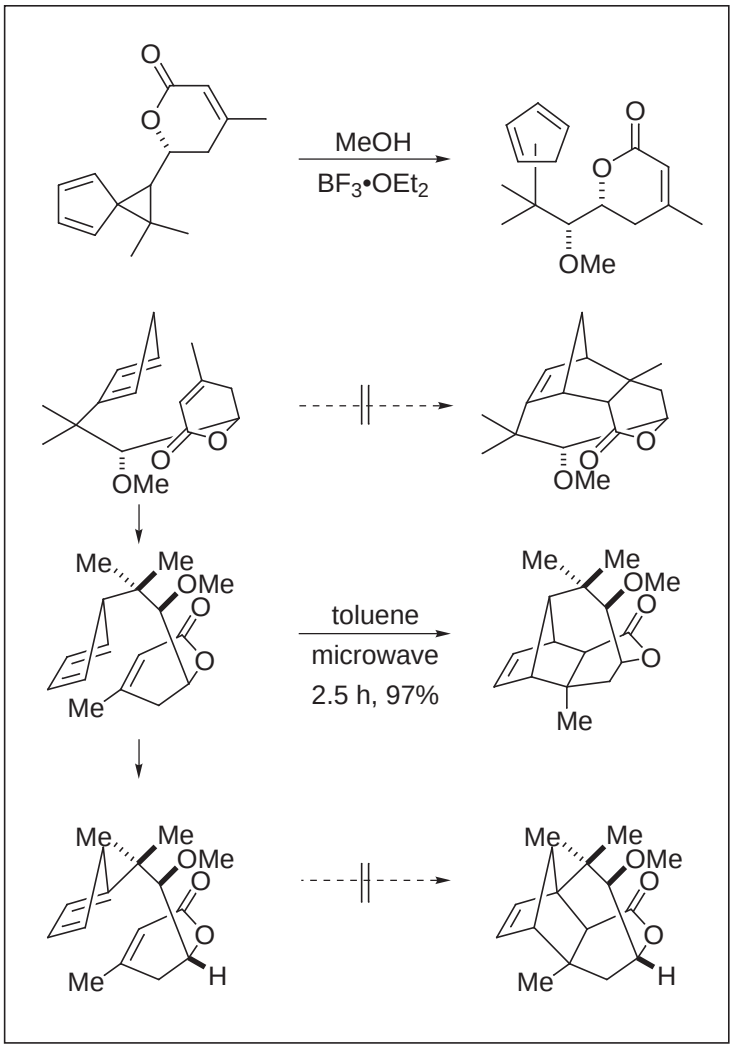
3-*exo-tet* cyclization



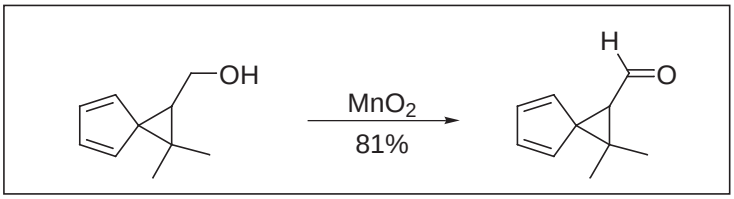
Barton Free Radical Deoxygenation
- mild method for removal of alcohols



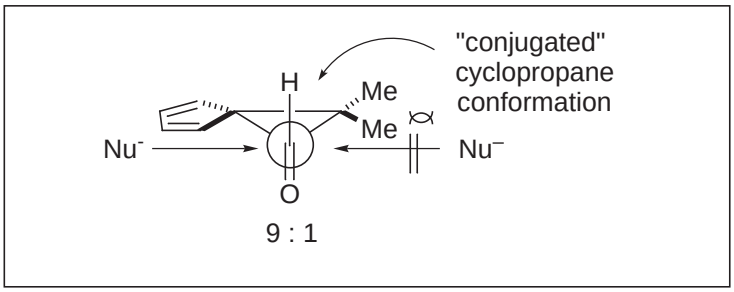
Acetate Pyrolysis
- a retro ene reaction
- comparable to the sulfoxide *syn* elimination (Trost) which is activated by an adjacent EWG.
- comparable to the selenoxide *syn* elimination (Reich) which is milder, faster and proceeds at lower temperature



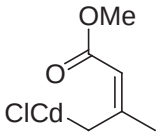
Intramolecular Diels-Alder Reaction
- constraints of the 6-membered ring precludes reaction from the other cyclopentadiene isomers and lactone stereochemistry dictates π-facial selectivity

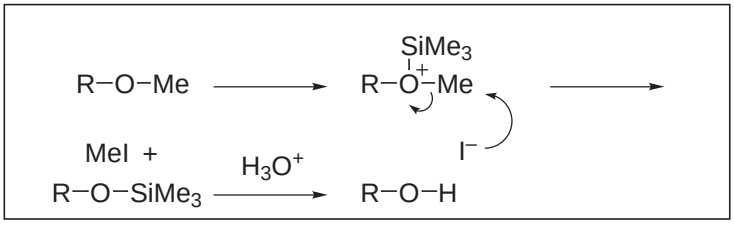


- MnO_2 serves to oxidize cyclopropyl alcohol analogous to allylic alcohol oxidation



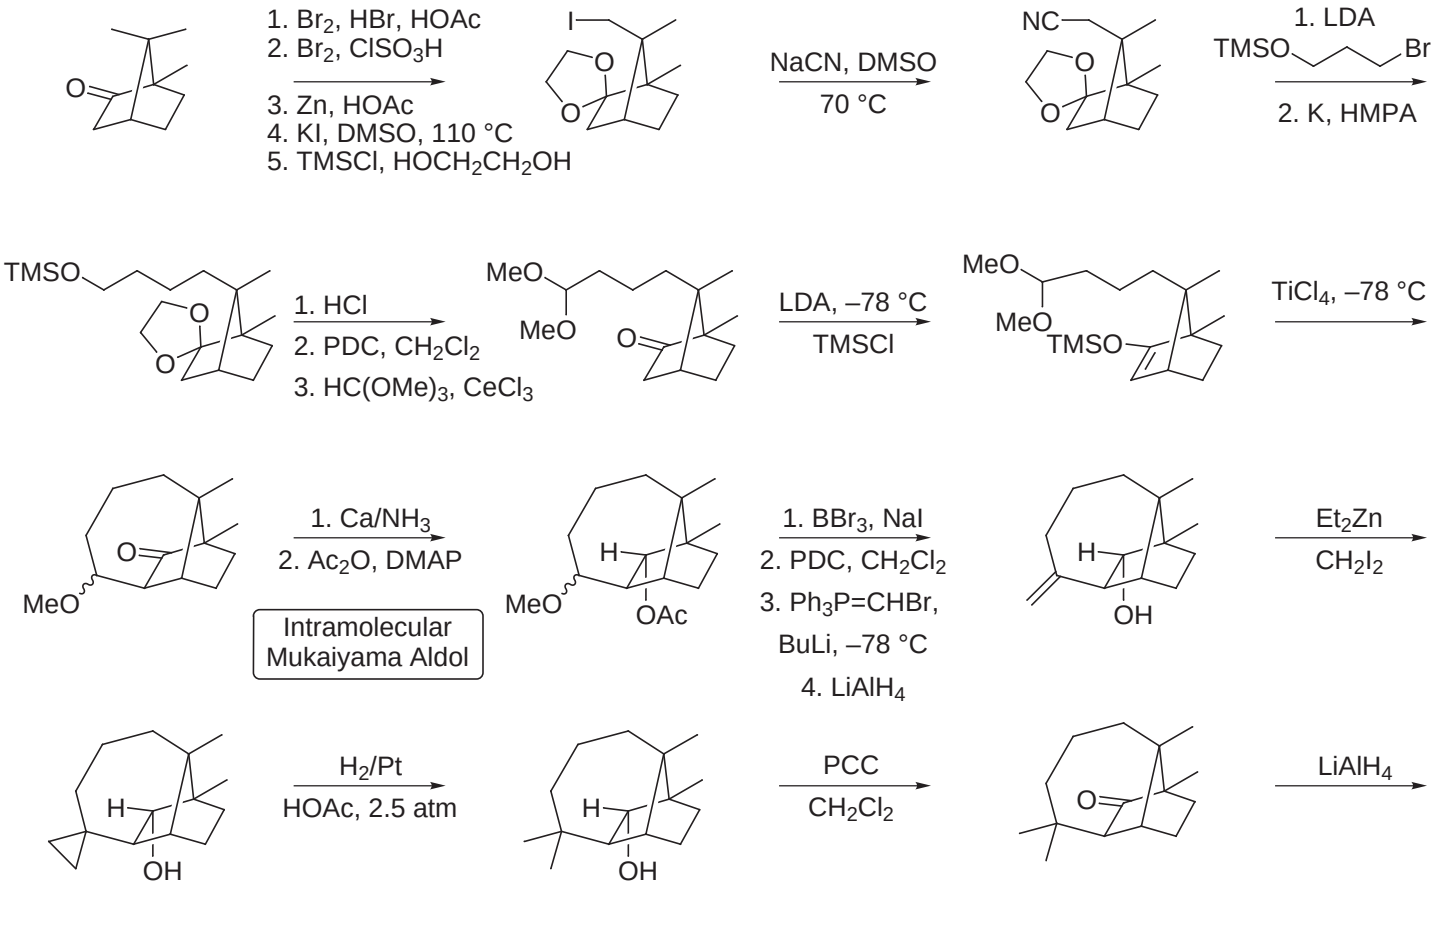
- Cadmium reagent for α-versus γ-enolate reaction
- Diastereoselective addition

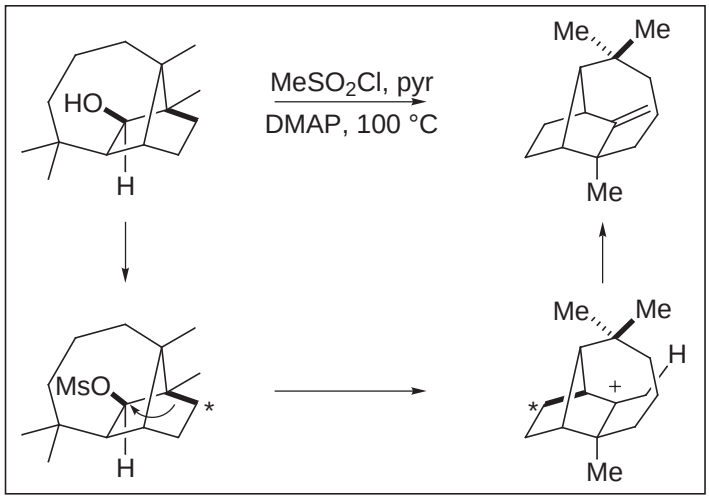




NaI-TMSCl deprotection
- dealkylative S_N2 methyl ether deprotection

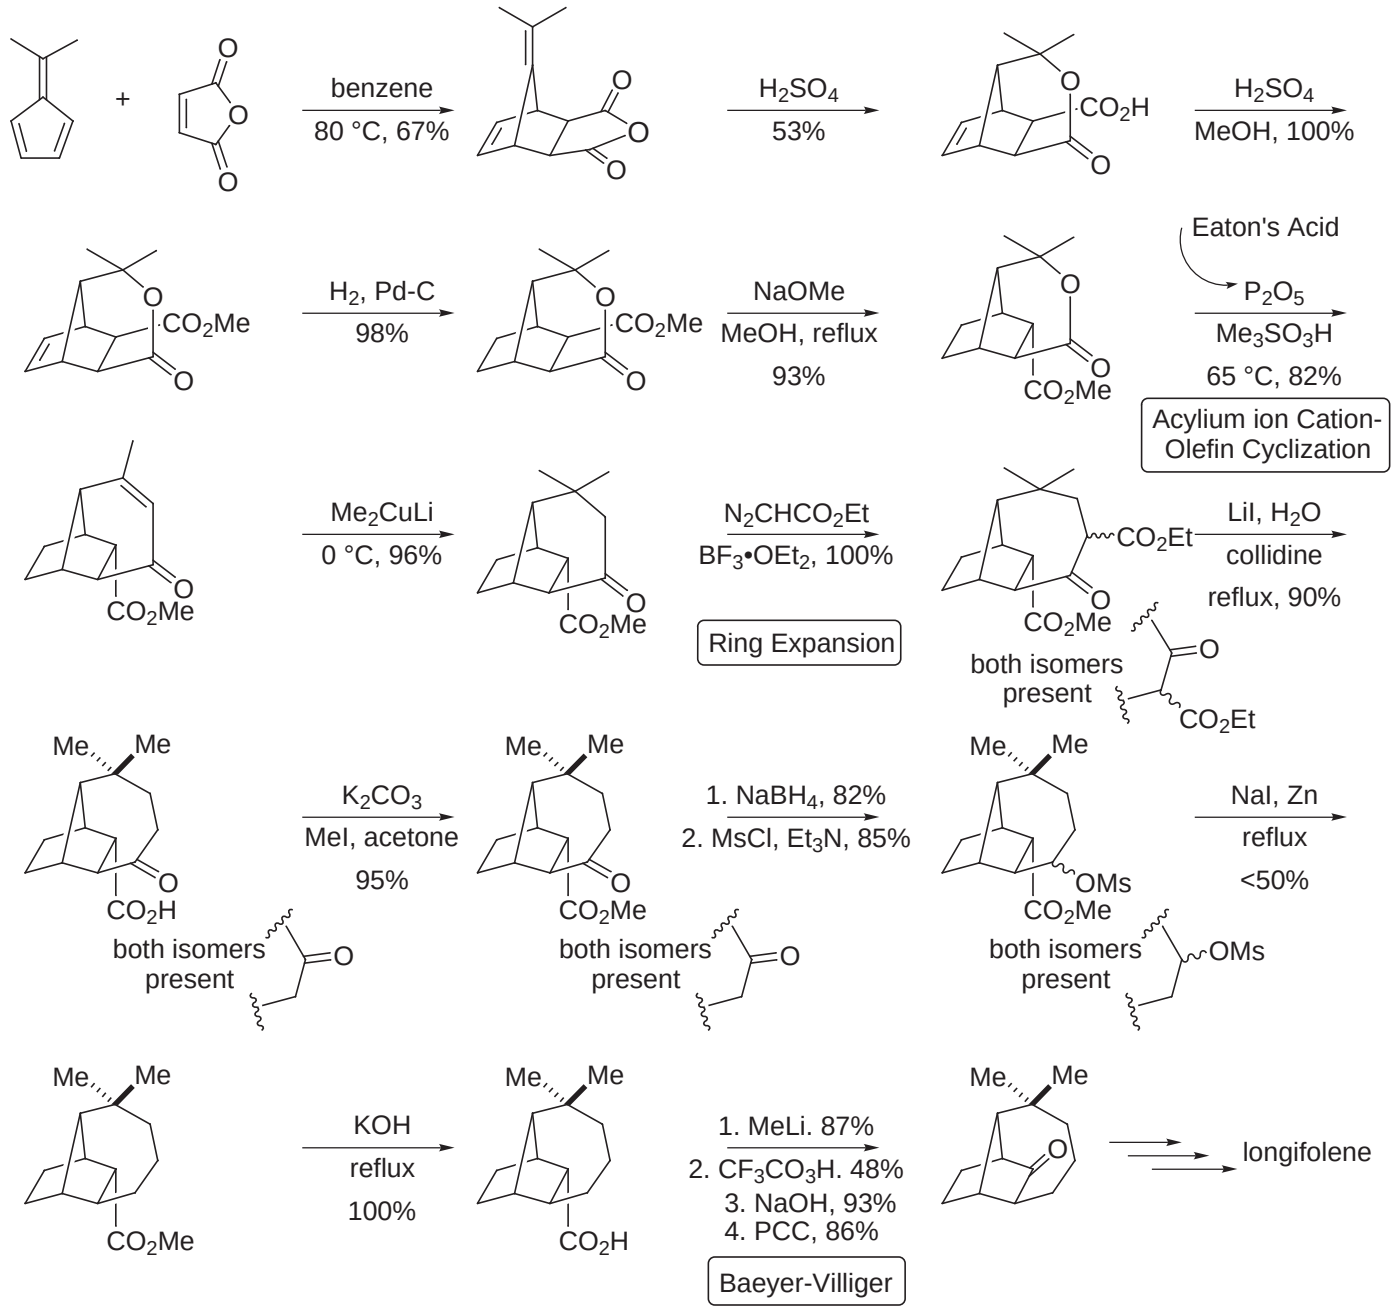
9. Kuo Synthesis: *Can J. Chem.* **1988**, *66*, 1794. Intramolecular Aldol Addition
Wagner-Meerwein Rearrangement

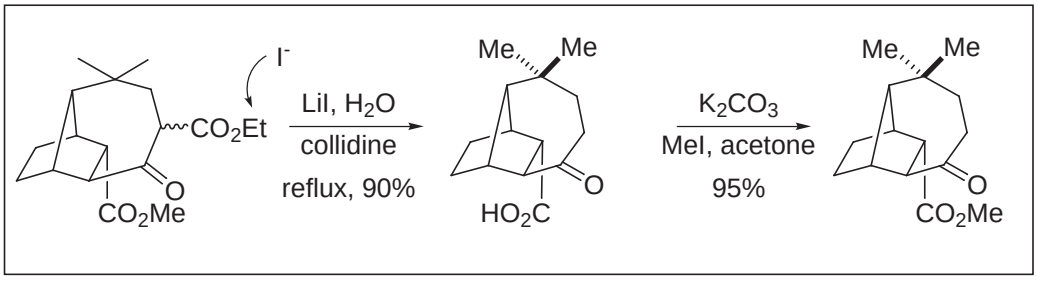




Wagner-Meerwein Rearrangement

10. Ho Synthesis: *Can J. Chem.* **1992**, *70*, 1375. Ethyl Diazoacetate Ring Expansion
Alkylative Esterification





- S_N2 Dealkylative Deesterification followed by decarboxylation of the β-keto acid
- Alkylative Esterification

XIV. Combinatorial Chemistry

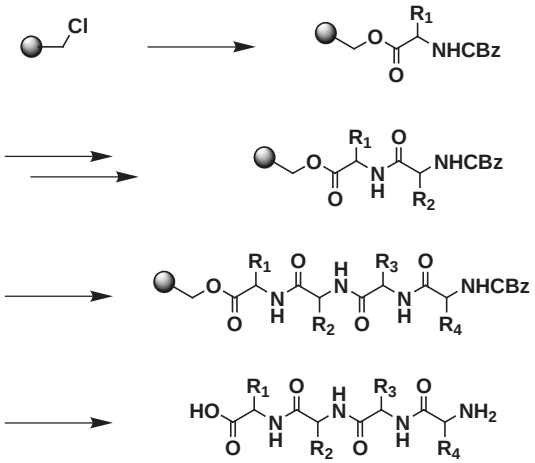
Solid Phase Peptide Synthesis

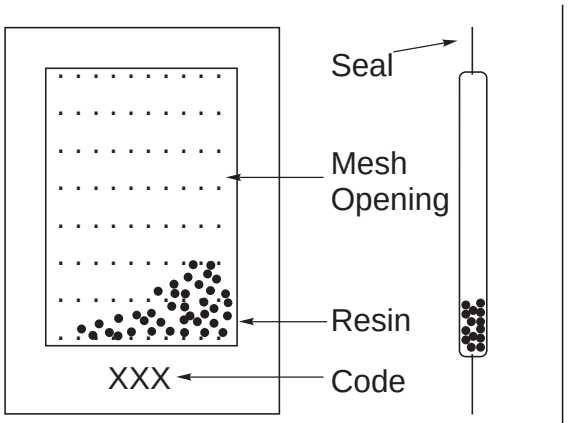


- Attach first amino acid to (chloromethylated) polymer bead
- Deprotect (HBr), Couple (DCC), Cap (acetic anhydride)
- Repeat coupling cycle
- Deprotect, Saponify, Purify

- Allows excess of reagents and reactants to force reaction to completion
- Removal of reagents, reactants and byproducts by filtration

Merrifield, R. B. *J. Am. Chem. Soc.* **1963,** *85,* 2149.
Nobel Prize, 1984 *"for his development of methodology for chemical synthesis on a solid matrix"*

Tea-Bag Method



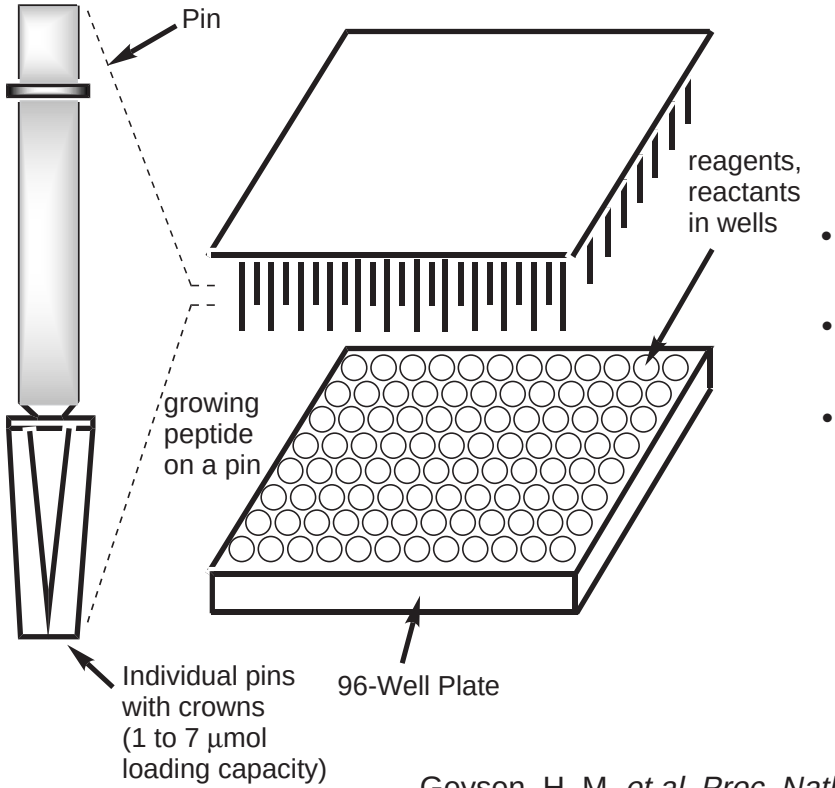
- 10 to 20 mg of 248 different 13-residue peptides
- Sequence

1. Deprotect
2. Wash
3. Couple
4. Wash
5. HF Cleave

Wash

Houghten, R. A. *et al.Proc. Natl. Acad. Sci. USA* **1985**, *82*, 5131.

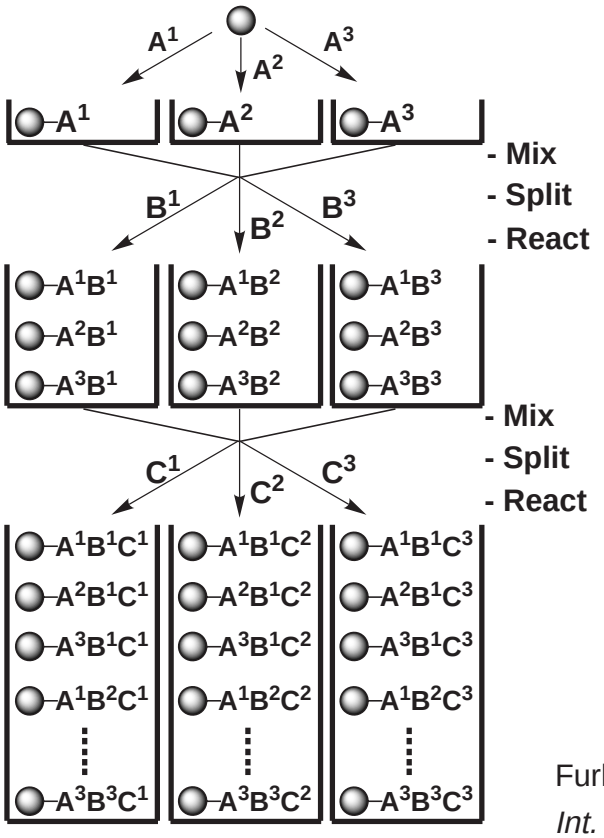
Multipin Peptide Synthesis



- Synthesize on polyacrylate-grafted polyethylene rods
- Utilize conventional solid phase synthesis methods
- Preparation of up to 10,000 spatially separate compounds using inexpensive equipment and readily available automation

Geysen, H. M. *et al. Proc. Natl. Acad. Sci. USA* **1984**, *81,* 3998.
Zuckermann, R. N. *et al. Bioorg. Med. Chem. Lett.* **1993**, *3,* 463.

Split and Mix Solid Phase Synthesis (Split-Method, Portioning-Mixing Method)



- Solid support is divided before each coupling cycle
- Equimolar mixtures of peptides
- Cannot conduct direct mixture synthesis on solid phase due to differential reaction rates
- One unique peptide on each bead

$$N = n_1 \times n_2 \times n_3 \times \ldots\ldots n_m$$

N = number of products after each cycle

n = number of reactants in each cycle

Furka, A. *et al. Bioorg. Med. Chem. Lett.* **1993**, *3,* 413; *Int. J. Peptide Prot. Res.* **1991**, *37*, 487.

Generation of Combinatorial Antibody Libraries

Use of bacteriophage lambda vector to express in *E. coli* a combinatorial library of Fab fragments

Sequence:

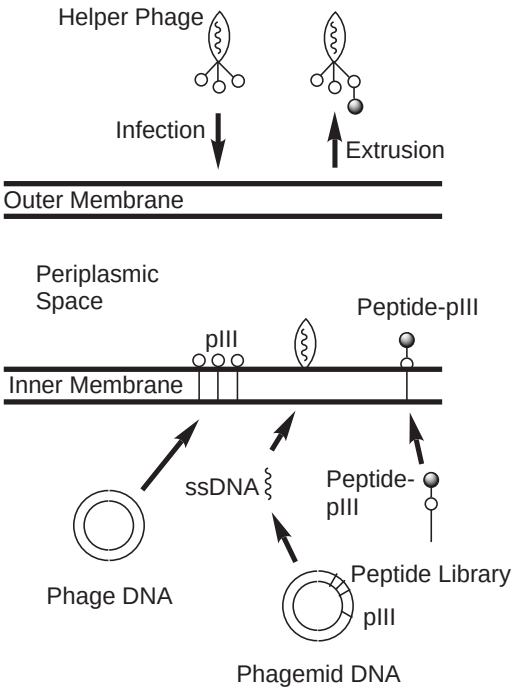
First step: Separation of heavy and light chain libraries which are constructed in λHc2 and λLc1

Second Step: Combination of two libraries are combined at the antisymmetric *Eco R* sites present in each vector

This results in a library of clones each of which potentially coexpresses a heavy and a light chain

Lerner, R. A. *et al. Science* **1989**, *246,* 1275.

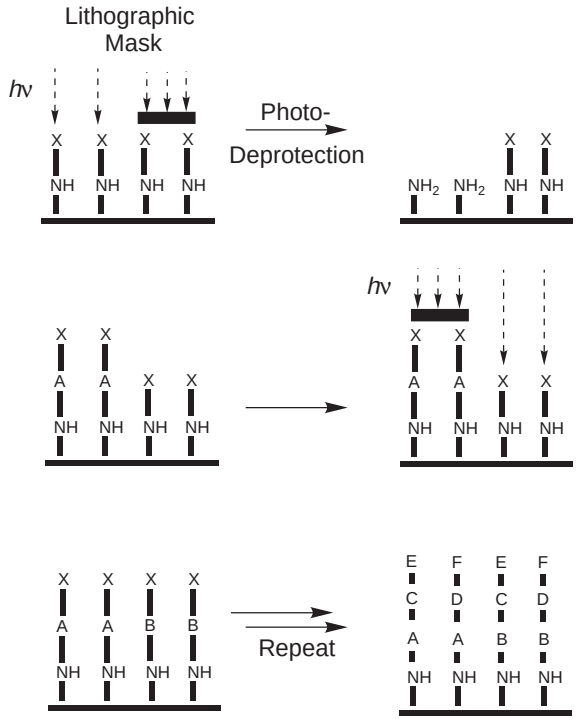
Phage Display



- The general concept is one in which a library of peptides is presented on the surface of a bacteriophage such that each phage displays a unique peptide and contains within each genome the corresponding DNA sequence
- Introduction of randomized DNA into gene III of filamentous phage ⟶ Expression of the corresponding peptides at the *N* terminus of the absorption peptide (pIII)
- Very quick and efficient generation of large combinatorial libraries of peptide fragments
- Screen by panning and enrichment
- Identify by DNA sequence

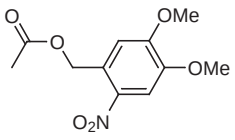
Smith, G. P. *et al. Science* **1990**, *249*, 386.

Very Large Scale Immobilized Polymer Synthesis (VLSIPS)



- Light-directed spatially addressable parallel chemical synthesis
- Nitroveratryloxycarbonyl (NVOC) as a photolabile protecting group

X =

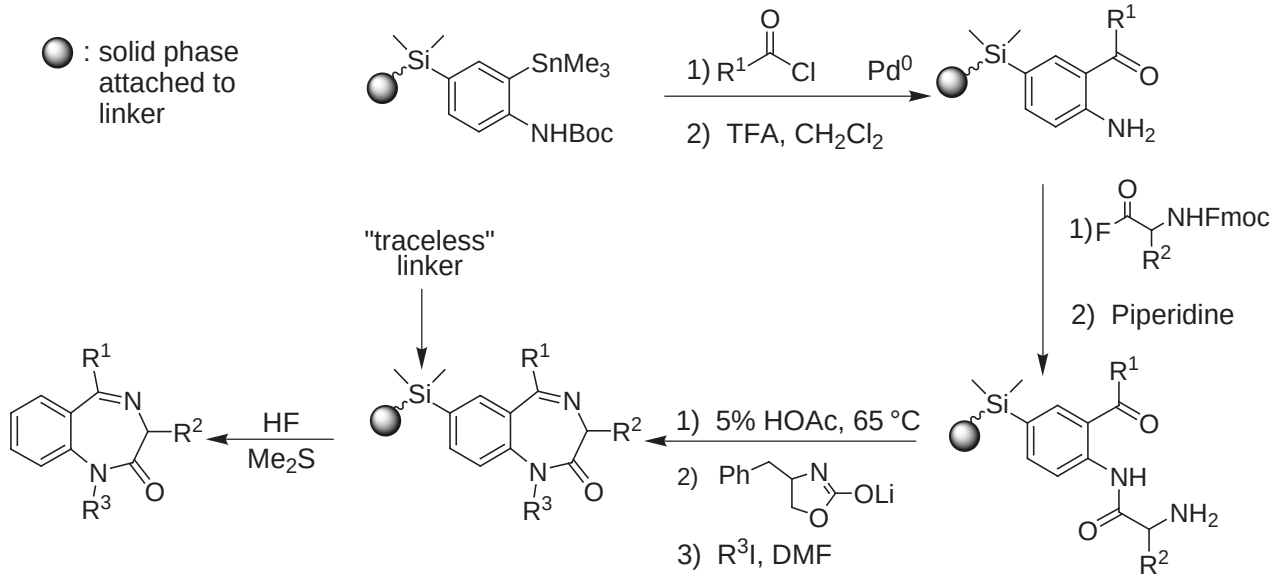


- Binary masking yields 2^n compounds in *n* chemical steps

Fodor, S. P. A.; Pirrung, M. C. *et al. Science* **1991**, *251*, 767.

Solid Phase Synthesis of 1,4-Benzodiazepines

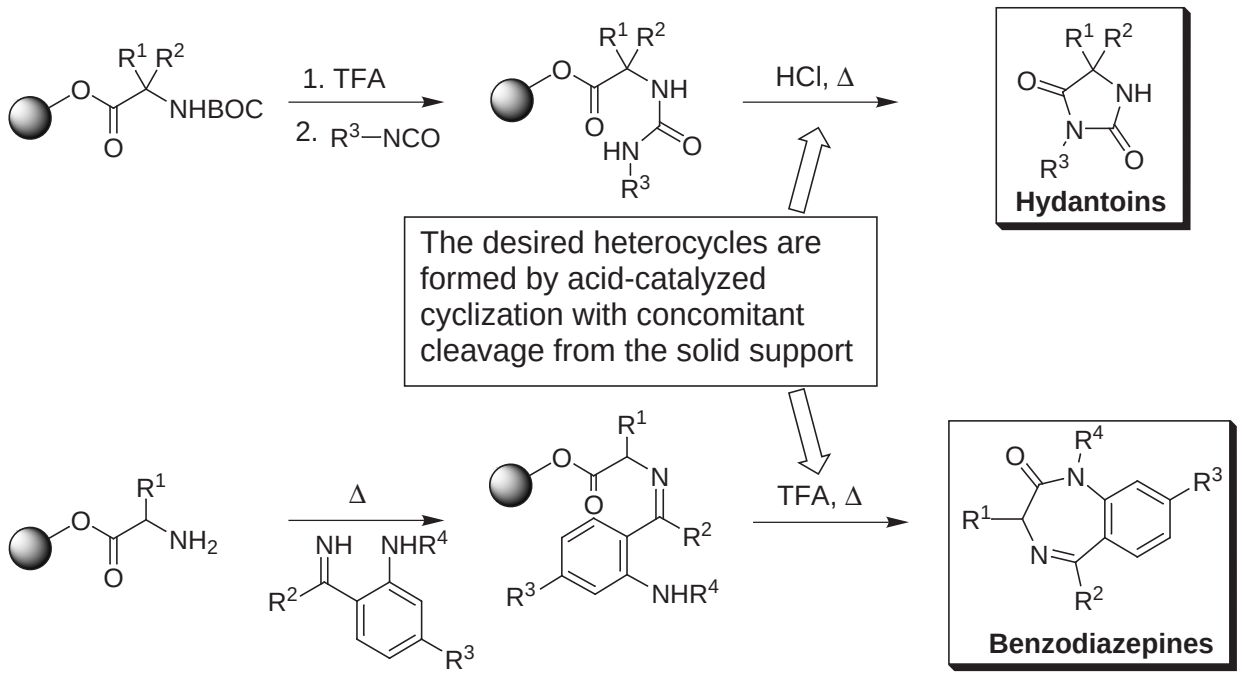
- Application of solid-phase combinatorial synthesis to non-oligomeric compounds



Ellman, J. A. *et al. J. Am. Chem. Soc.* **1992,** *114,* 10997.

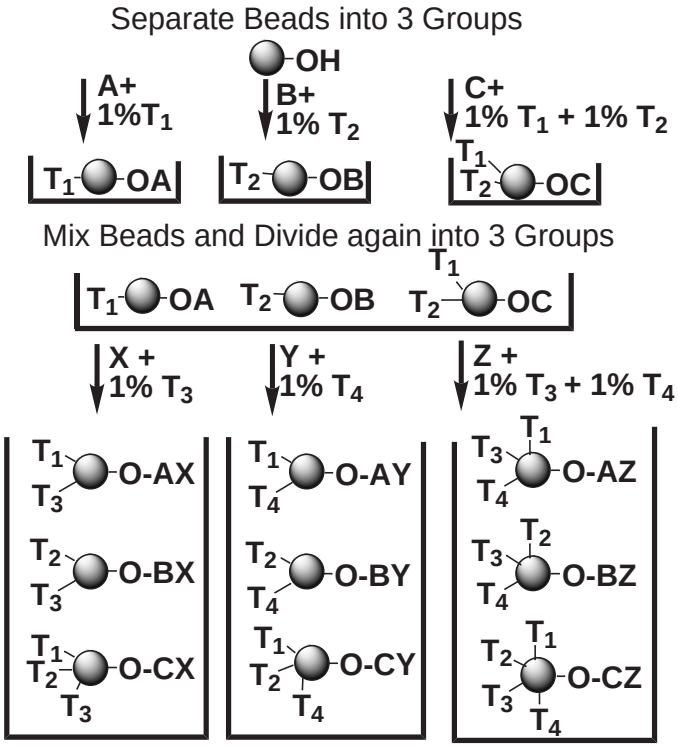
DeWitt, S. H. *et al. Proc. Natl. Acad. Sci. USA* **1993,** *90,* 6909.

Resin Release Only of Product



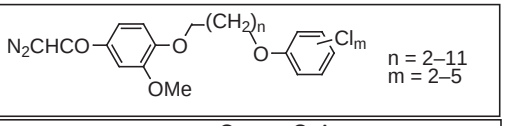
DeWitt, S. H. *et al. Proc. Natl. Acad. Sci. USA* **1993,** *90,* 6909.

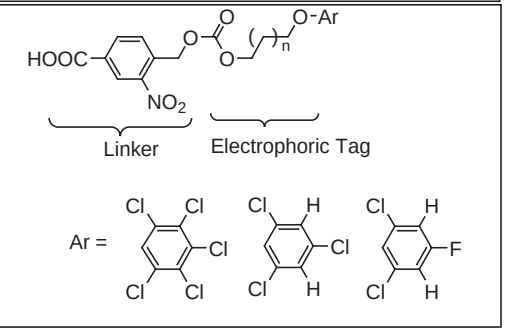
Split Synthesis ENCODED with Tagging Molecules (T_1–T_4)



Tagging Molecules

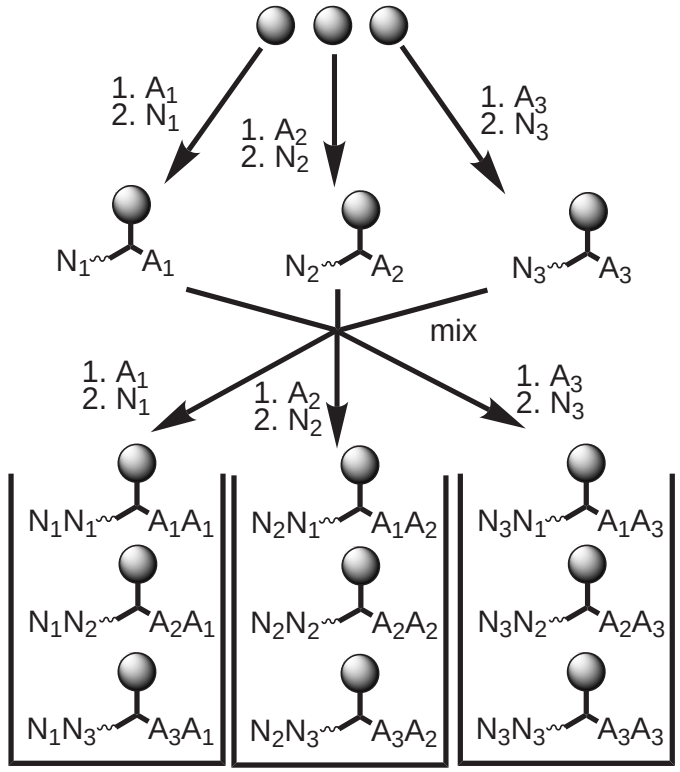
1. Chemically inert
2. Encoding by attachment to the beads
3. After release, analyzed by
   Capillary Gas Chromatography
   using Electron Capture Detection
   (ECGC) on femtomolar scales
   from single beads
4. Identity only





Still, W. C. *et al. Proc. Natl. Acad. Sci. USA* **1993**, *90*, 10922; *Acc. Chem. Res.* **1996**, *29*, 155.

Nucleotide Encoding



- CPG beads
- Linker Unit
- PCR Primer

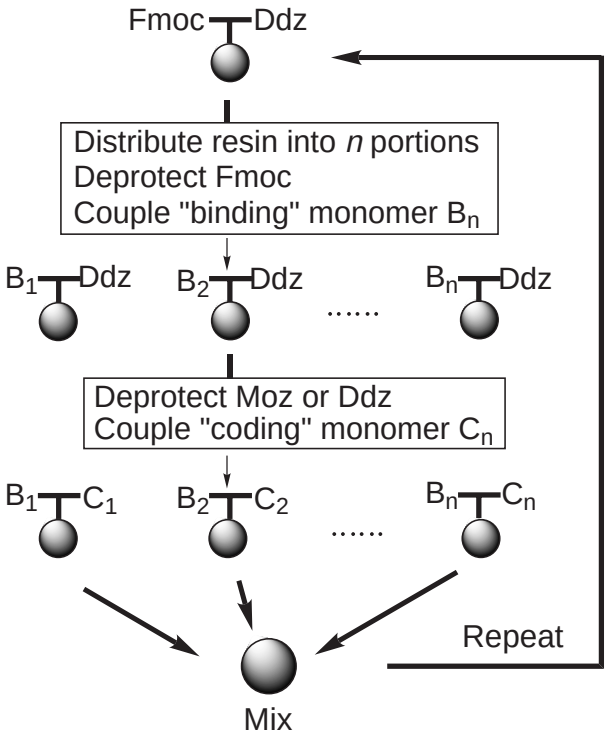
A_1, A_2, A_3: Amino Acids

N_1, N_2, N_3: Encoding Nucleotides

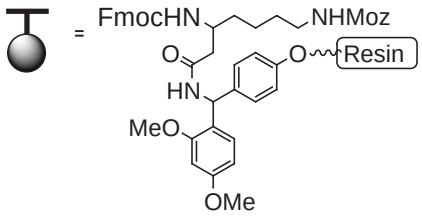
- Tag attached to molecule, not bead
- PCR enrichment: sensitivity and screening by panning and enrichment
- Bonus: nucleotide tagging could be used for identification as well

Janda, K. D. *et al. J. Am. Chem. Soc.* **1993**, *115*, 9812.
Brenner, S.; Lerner, R. A. *Proc. Natl. Acad. Sci.* USA. **1992**, *89*, 5381.

Peptide Encoding



B: Fmoc protected, base-labile monomers
C: Ddz-protected, acid-labile monomers, which give reproducibly strong signals upon Edman sequencing

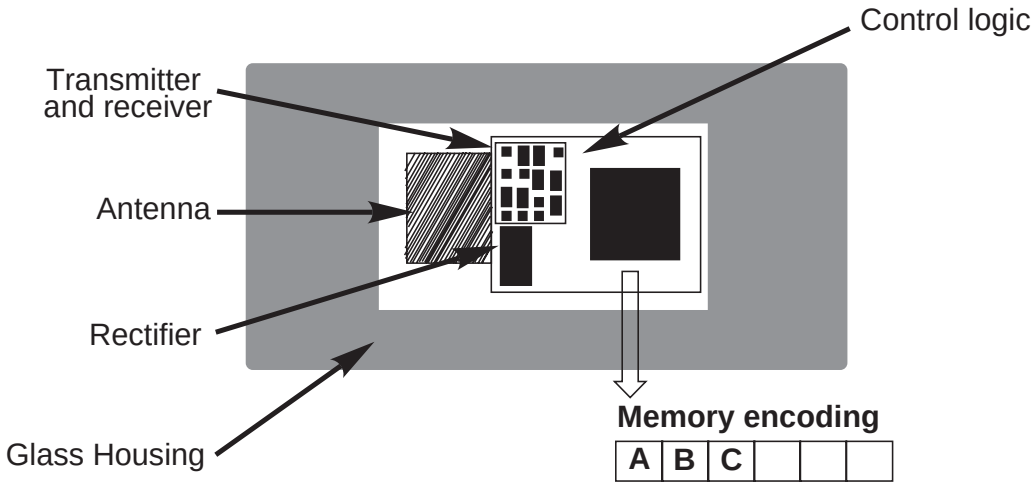


- Identity only

Zuckermann, R. N. *et al. J. Am. Chem. Soc.* **1993**, *115*, 2529.

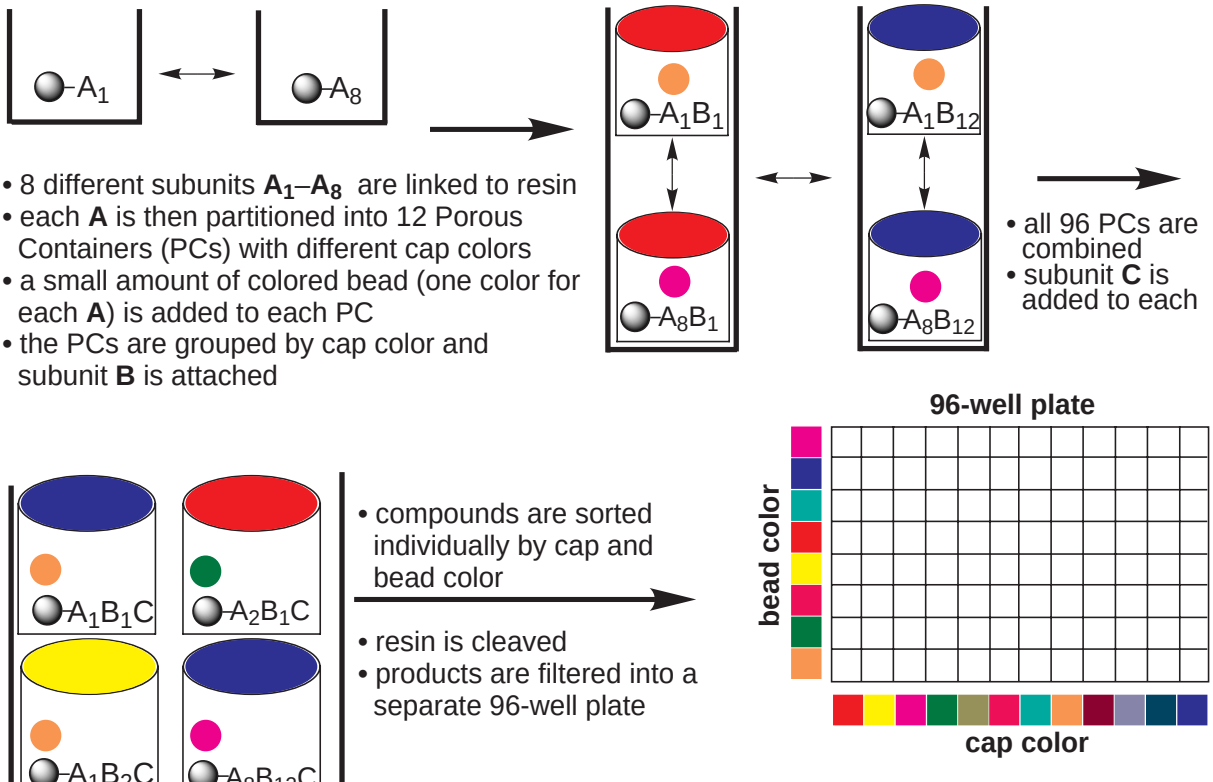
Electronic Encoding

- Radiofrequency memory chips allow libraries to be tagged in a machine-readable form
- The chips (8 x 1 mm) can be incorporated into various reaction platforms (e.g. beads, tubes, bags, pins or cans)



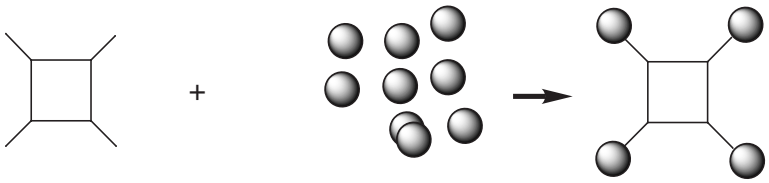
Nova, M.; Nicoloau, K. C. *et al. Angew. Chem., Int. Ed. Eng*. **1995**, *34*, 2289.
Armstrong, R. W. *et al. J. Am. Chem Soc.* **1995,** *117*, 10787.

Noncovalent Color-Coding Strategy



Guiles, J. W. *et al. Angew. Chem., Int. Ed. Eng.* **1998**, *37,* 926.

One-Step Mixture Synthesis and Deconvolution "Activated Core Approach"



Core molecules:
3 Tetraacid chlorides

Building blocks:
19 amino acids

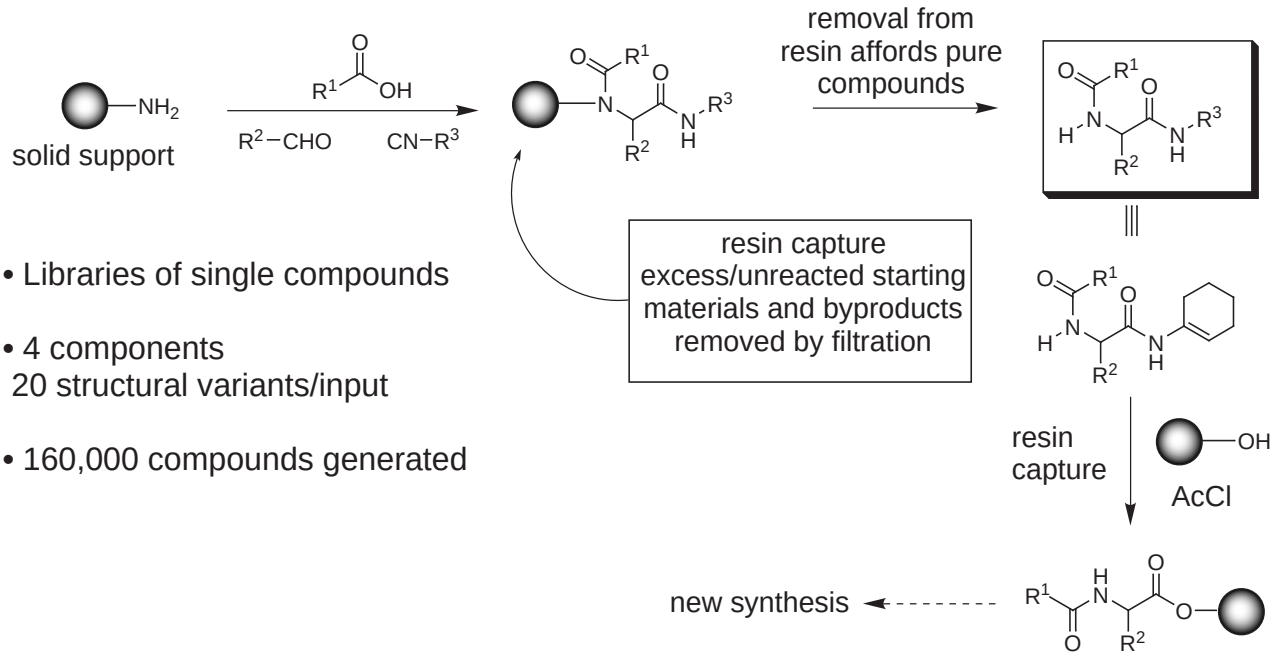
Library size:
A1: 11,191
A2: 65,341
A3: 1,330

Deconvolution by Omission Resynthesis

1. Libraries A1–A3 to find best core molecule
2. Sublibraries B1–B6 to find best 9 building block amino acids (AA)
3. Sublibraries C1–C7 to check if the selected 9 AA are the best combination
4. Sublibraries D1–D9 to find the best 5 AA
5. Sublibraries E1–E7 to find the best 3 or 4 groupings of the 5 AA
6. Sublibraries F1–F6 to find the best relative position of the 4 AA on the core
7. Single compounds G1–G3 synthesized and the best inhibitor of trypsin determined

Rebek, J. Jr., *et al. Chem. Biol.* **1995**, *2*, 171.

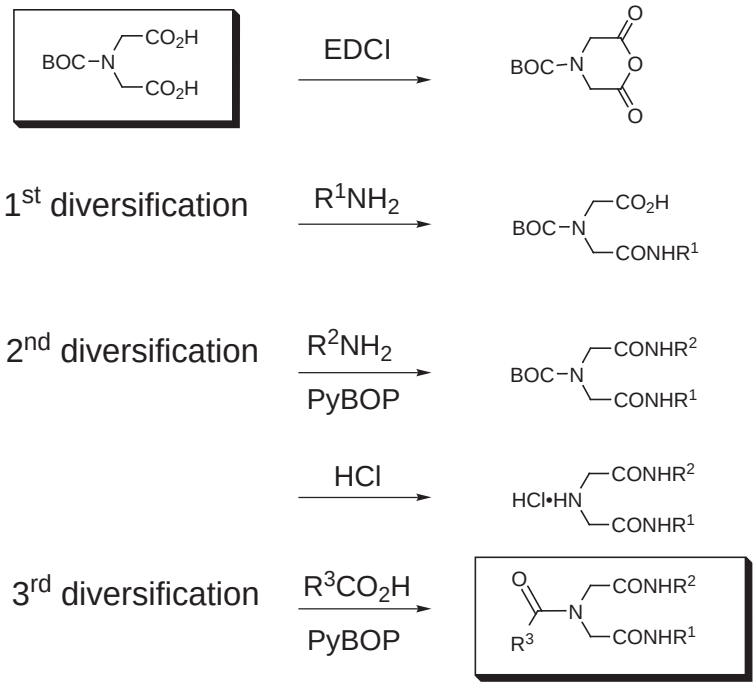
Multicomponent One-Step Mixture Synthesis



- Libraries of single compounds
- 4 components
  20 structural variants/input
- 160,000 compounds generated

Armstrong, R.W. *et al. Acc. Chem. Res.* **1996**, *29*, 123.
Ugi, I. *et al. Endeavour* **1994**, *18*, 115.

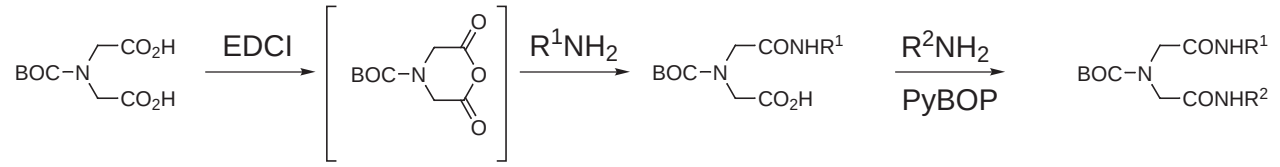
Multistep Solution Phase Synthesis of Combinatorial Libraries Purification via Liquid/Liquid or Liquid/Solid Extraction

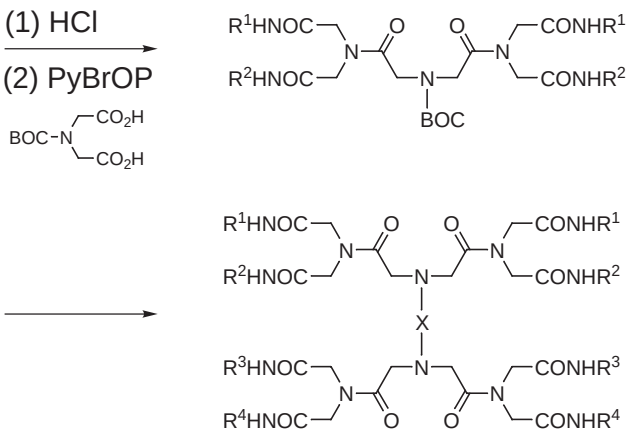


- Solvent, reagent byproducts, excess reagents and reactants removed through extraction with acid and/or base
- Liquid/solid extraction using ion exchange resins
- Products pure irrespective of yield
- 25–50 mg of products
- Multistep synthesis in format of:
  - individual compounds
  - small mixtures
  - large mixture synthesis

Boger, D. L. *et al. J. Am. Chem. Soc.* **1996**, *118*, 2567.

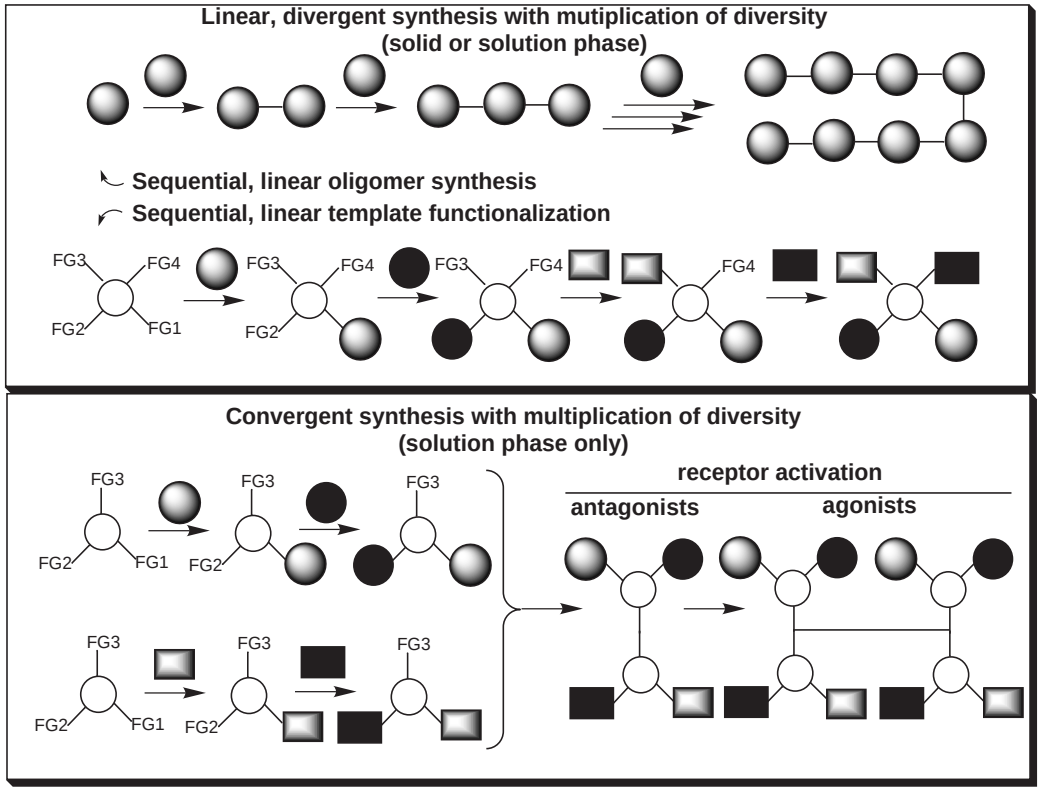
Multistep Convergent Solution Phase Combinatorial Synthesis





- The synthesis of large molecules is possible in only a few steps
- Purification at each step by acid/base extractions or solid/liquid extractions
- Solution phase only
- Multiplication of diversity
- Final dimerization has been achieved via peptide coupling with diacids or olefin metathesis

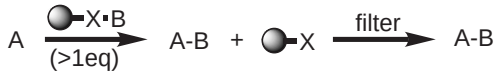
Boger, D. L. *et al. Tetrahedron* **1998**, *54*, 3955.
Boger, D. L. *et al. Bioorg. Med. Chem.* **1998**, *6*, 1347.



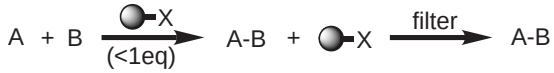
Boger, D. L. *et al. Tetrahedron* **1998,** *54*, 3955; *J. Am. Chem. Soc.* **1998**, *120*, 7220.

Polymer Supported Scavenging Reagents

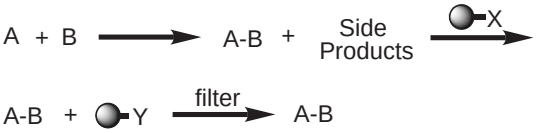
I. polymer-supported stoichiometric reagents



II. polymer-supported catalytic reagents



III. polymer-supported scavenging reagents (excess reagents, starting materials)

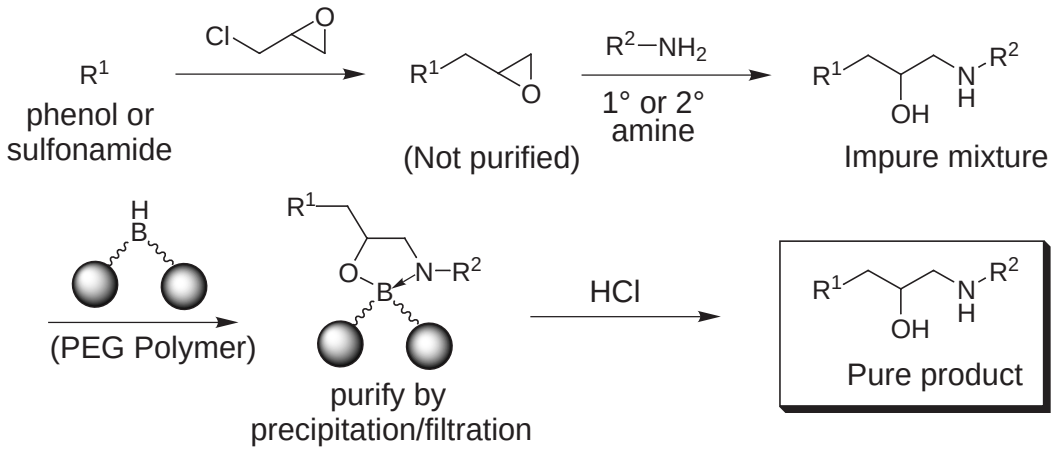


- Solve the purification problem in mixture synthesis
- Entrain impurities upon completion of solution-phase reactions, either covalently or ionically
- Covalent scavengers: nucleophile-electrophile
- Ionic scavengers: a series of anion and cation exchange resins (liquid-solid extraction)

Boger, D. L. *et al. J. Am. Chem. Soc.* **1996,** *118*, 2567.
Flynn, D. L. *et al. J. Am. Chem. Soc.* **1997,** *119,* 4874.
Hodges, J. C. *et al. J. Am. Chem. Soc.* **1997**, *119*, 4882.
Kaldor, S. W. *et al. Tetrahedron Lett.* **1996**, *37*, 7193.

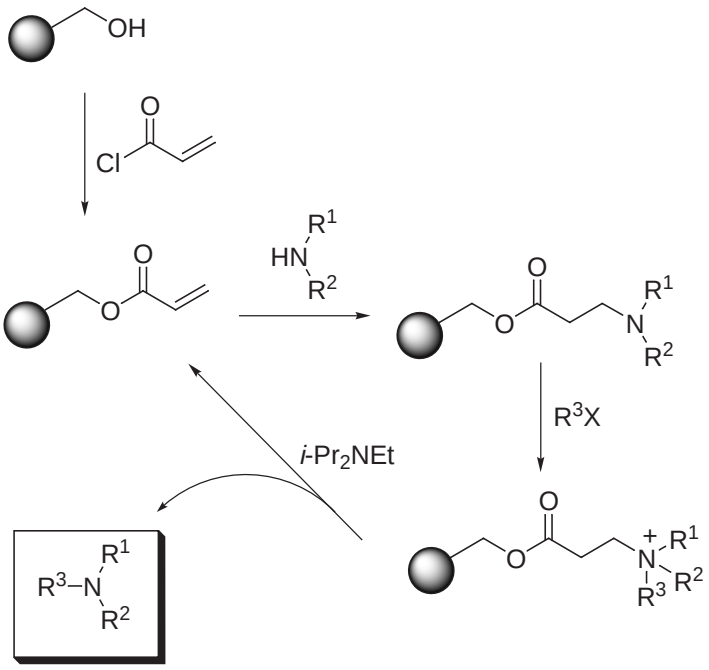
Resin Capture of Product ("Fishing Out" Principle)

- Libraries of β-amino alcohols are synthesized by parallel synthesis in solution
- Purification is achieved by "fishing out" the desired products with a PEG-bound dialkylborane
- Precipitation of the polymer-bound product allows the removal of unreacted starting materials and any byproducts
- Treatment with HCl releases the product from the polymer support in high purity



Janda, K. D. *et al. J. Org. Chem.* **1997**, *63*, 889.

Resin Release Only of Product



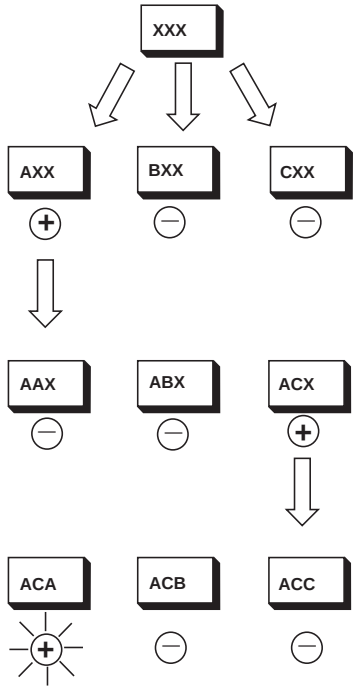
- A wide range of 3° amines can be synthesized on solid support
- The product is released via β-elimination
- Only the activated (quaternary) product is released, ensuring purities >95%
- After cleavage of product, the resin is regenerated and can be reused

Morphy, J. R. *et al. J. Am. Chem. Soc.* **1997**, *119*, 3288.

Iterative Deconvolution

SURF Deconvolution

(Synthetic Unrandomization of Randomized Fragments)



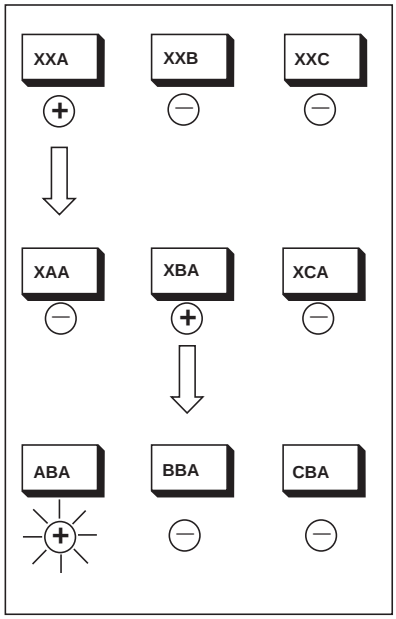
- Iterative deconvolution was first applied to peptide libraries
- The SURF procedure was described for nucleotide libraries
- Libraries are synthesized on solid phase by split synthesis
- Repetitive synthesis and screening of increasingly simplified sets.
- At each step of the deconvolution an additional position is known
- Activity increases at each step, enhancing the accuracy of identification
- Most potent library member guaranteed to be found and multiple hits lead to multiple parallel deconvolutions
- Time between synthesis of libraries and hit identity long and cumbersome

Houghten, R. A. *et al. Nature* **1991**, *354*, 84.

Ecker, D. J. *et al. Nucleic Acids Res.* **1993,** *21***,** 1853.

Recursive Deconvolution

- The library (XXX) is synthesized by split synthesis
- At each stage 1/3 of the material is stored and labeled as a partial library
- These stored partial libraries are used to deconvolute the full library



Test 3 pools for activity

Couple **A** to saved and catalogued **XA**, **XB**, and **XC**

Test 3 pools for activity

Couple **BA** to saved and catalogued **A**, **B** and **C**

Test 3 pools for activity

Janda, K. D. *et al. Proc. Natl. Acad. Sci. USA* **1994**, *91*, 11422.

Positional Scanning of Synthetic Peptide Combinatorial Libraries

- Deconvolution libraries produced upfront for testing
- Identifies most active residue at each position in one round of testing
- Screen looking for increases in activity
- This combination is not always the most potent (ca. 20–40% of time)
- Best for identifying multiple hits in a library including weak activities
- Requires mixture synthesis, not suited for solid phase

O1	**X**	**X**	**X**	**X**	**X-NH_2**
X	**O2**	**X**	**X**	**X**	**X-NH_2**
X	**X**	**O3**	**X**	**X**	**X-NH_2**
X	**X**	**X**	**O4**	**X**	**X-NH_2**
X	**X**	**X**	**X**	**O5**	**X-NH_2**
X	**X**	**X**	**X**	**X**	**O6-NH_2**

O = individual component

X = mixture

Houghten, R. A. *et al. Nature* **1991,** *354,* 84.

Deletion Synthesis Deconvolution

- Deconvolution libraries produced upfront for testing
- Identifies most active residues at each position in one round of testing
- Screen library for loss of activity versus full mixture
- Best at identifying potent hits in a library, poor at identifying weak or multiple hits
- Requires mixture synthesis, not suited for solid phase
- Also suited for symmetrical libraries not capable of being addressed by scanning deconvolution

dA1	X	X	X
dA2	X	X	X
dA3	X	X	X
dA4	X	X	X

X	X	dC1	X
X	X	dC2	X
X	X	dC3	X
X	X	dC4	X

X	dB1	X	X
X	dB2	X	X
X	dB3	X	X
X	dB4	X	X

X	X	X	dD1
X	X	X	dD2
X	X	X	dD3
X	X	X	dD4

dA1 = mixture minus A1 (delete A1)

X = mixture

Solid Phase or Solution Phase Combinatorial Synthesis?

Solid Phase

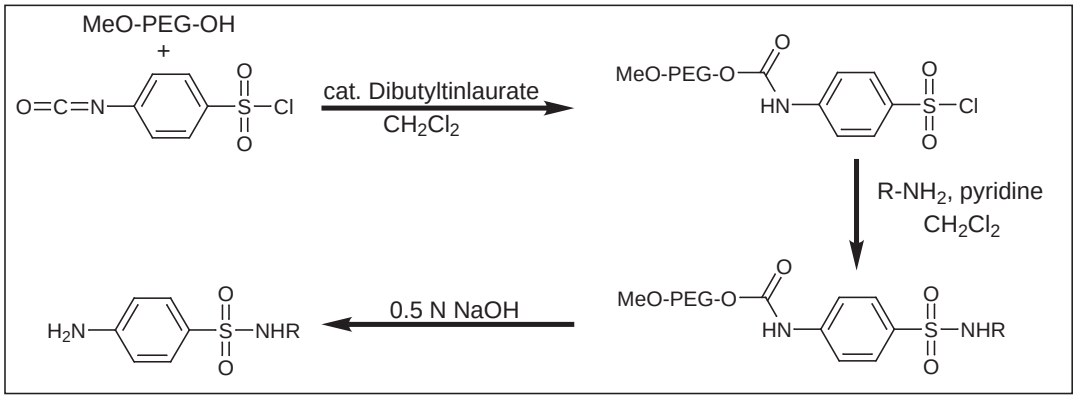
+ Simple removal of excess reagents and reactants
+ Automation straightforward
+ Split and mix synthesis
+ Pseudo-dilution effects
− Adapt chemistry to solid phase and develop linking/cleaving strategies
− Reaction monitoring difficult
− No purification possible
− Linear, cannot conduct convergent synthesis
− Limited scale
− Cannot conduct mixture synthesis

Solution Phase

+ Chemistry not limited by support or linker
+ Monitor by traditional techniques
+ Purification possible after each step
+ Unlimited amounts (scales) available
+ Avoids extra steps for linking, etc
+ Automation by liquid-liquid techniques
+ Mixture or parallel synthesis
+ Convergent or linear synthesis
− Removal of excess reagents and reactants limits scope

Combinatorial Synthesis Using Soluble Polymers

- Reactions were performed in the homogeneous liquid-phase solution using soluble polymer (MeO-PEG: polyethylene glycol monomethyl ether)
- Homogeneous reaction conditions overcome the difficulties of solid-phase combinatorial synthesis
- Isolation can be accomplished by precipitation at each stage
- Intermediates can be purified by conventional means (*e.g.* chromatography)
- Analysis of intermediates is possible by conventional means (*e.g.* NMR)



Janda, K. D. *et al. Proc. Natl. Acad. Sci. USA* **1995,** *92,* 6419.

Fluorous Phase Combinatorial Synthesis

- Fluorous liquids: Immiscible with both water and organic solvents
- Simple purification of products by three-phase liquid–liquid extraction
- Accomplishment of a series radical addition by homogeneous fluorous-phase combinatorial synthesis

Reagents on fluorous phase
Substrates on fluorous phase

Angew. Chem., Int. Ed. Eng. **1998**, 37, 1175.

A Combinatorial Approach to Materials Discovery

Application of the combinatorial approach to the discovery of new solid-state materials with novel physical or chemical properties such as magnetoresistance or high-temperature superconductance.

Substrates: polished MgO or $LaAlO_3$ single crystals

Sputtering Targets: CuO, Bi_2O_3, CaO_3, PbO, $SrCO_3$, Y_2O_3, and $BaCO_3$

Generation of a 128-member binary library using 7 deposition-masking steps

Superconducting materials: $BiSrCaCuO_x$ and $YBa_2Cu_3O_x$

(Binary masks used for library synthesis)

Schultz, P. G. *et al. Science* **1995**, *268*, 1738.

Comparison of Combinatorial Chemistry Techniques

Technique	Single compound /mixture	Speed of synthesis	SAR retrieval	Utility
parallel synthesis	single	slow	fast	lead optimization
mixture synthesis (scanning/deletion deconvolution)	mixture	fast	slow (fast)	lead identification
parallel arrayed mixture	mixture	moderate	moderate	lead identification
split and mix	mixture (one compound per bead)	moderate	slow	lead identification lead optimization
chemically encoded mix and split	mixture (one compound per bead)	moderate	moderate	lead identification lead optimization
mix and sort (microreactors)	single	moderate	fast	lead optimization lead identification
